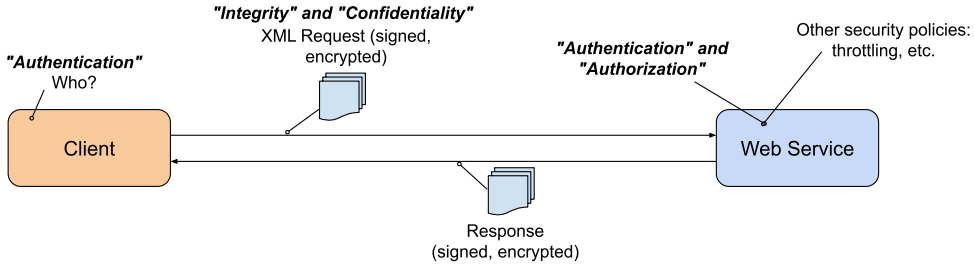
Modified: Sun Mar 24 2019, 23:17:03
Humla v0.3

Overview

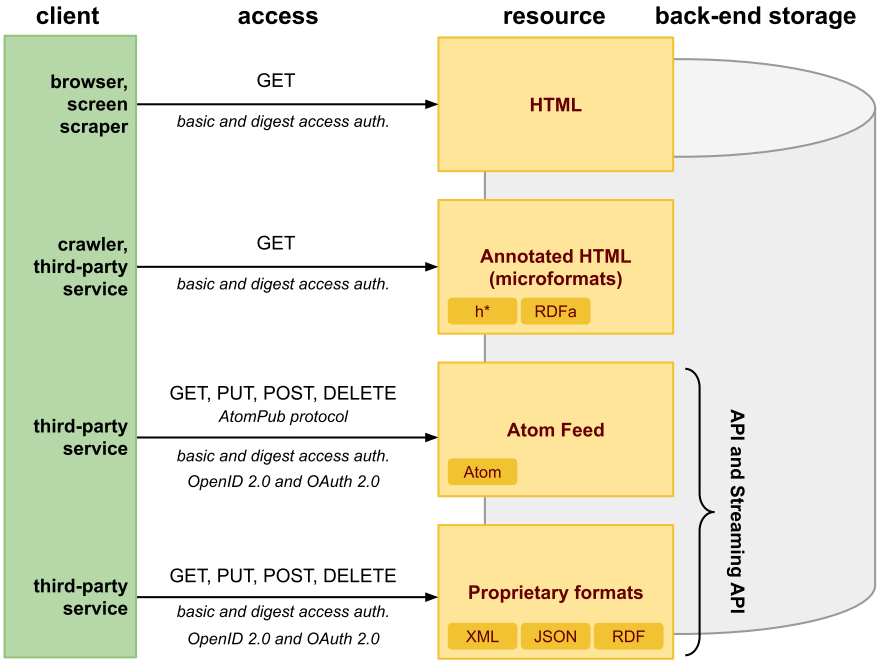
- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
- OpenID

Web Service Security Concepts

- Securing the client-server communcation
  - *Message-level security*
  - *Transport-level security*
- Ensure
  - *Authentication – verify a client's identity*
  - *Authorizaton – rights to access resources*
  - *Message Confidentiality – keep message content secret*
  - *Message Integrity – message content does not change during transmission*
  - *Non-repudiation – proof of integrity and origin of data*



Data on the Web



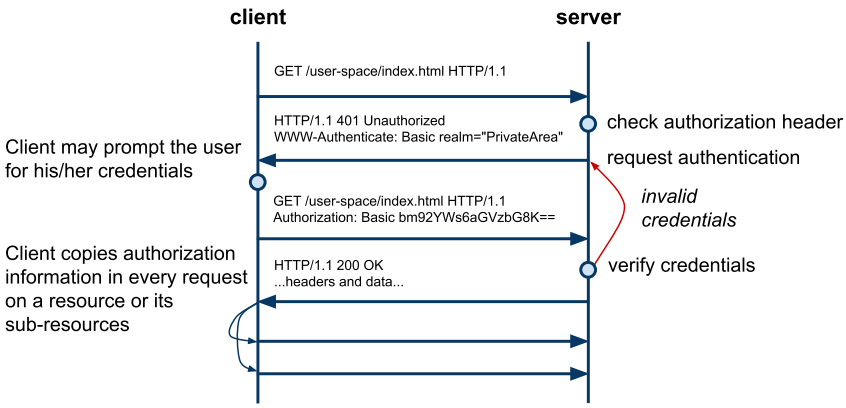
Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
- OpenID

Authentication and Authorization

- Authentication
  – *verification of user's identity*
- Authorization
  – *verification that a user has rights to access a resource*
- Standard: HTTP authentication
  – *HTTP defines two options*
    → *Basic Access Authentication*
    → *Digest Access Authentication*
  – *They are defined in*
    → *RFC 2616: Hypertext Transfer Protocol – HTTP/1.1*
    → *RFC 2617: HTTP Authentication: Basic and Digest Access Authentication*
- Custom/proprietary: use of cookies

Basic Access Authentication



- Realm
  - *an identifier of the space on the server (~ a collection of resources and their sub-resources)*
  - *A client may associate a valid credentials with realms such that it copies authorization information in requests for which server requires authentication (by* `WWW-Authenticate` *header)*

Basic Access Authentication – Credentials

- Credentials
  - *credentials are base64 encoded*
  - *the format is:* `username:password`

```
1  # to encode in linux
2  echo "novak:heslo" | base64
3  > bm92YWs6aGVzbG8K
4
5  # and to decode
6  echo "bm92YWs6aGVzbG8K" | base64 -d # use capital "D" in OS X
7  > novak:heslo
```

- Comments
  - *When SSL is not used, the password can be read*
  - *An attacker can repeat interactions*

Digest Access Authentication

- RFC 2617 – Basic and Digest Access Authentication
  - *No password between a client and a server but a hash value*
  - *Simple and advanced mechanisms (only server-generated nonce value – replay-attacks or with client-generated nonce value)*
- Basic Steps
  1. *Client accesses a protected area*

```
> GET / HTTP/1.1
```

  2. *Server requests authentication with* `WWW-Authenticate`

```
< HTTP/1.1 401 Unauthorized
< WWW-Authenticate: Digest realm="ProtectedArea",
  nonce="BbdQof3DBAA=a293ff3d724989371610f03015f2d23f3cd2c045",
  algorithm=MD5, domain="/", qop="auth"
```

  3. *Client calculates a response hash by using the realm, his/her username, the password, and the quality of protection (QoP) and requests the resource with* `authorization` *header*

```
> GET / HTTP/1.1
> Authorization: Digest username="novak", realm="ProtectedArea",
  nonce="BbdQof3DBAA=a293ff3d724989371610f03015f2d23f3cd2c045", uri="/",
  algorithm=MD5, response="c4ea2293aeb318826d1e533f363efd90", qop=auth,
  nc=00000001, cnonce="531ee8ba7f2a8fd1"
```

Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
- OpenID

Overview

- JSON Web Token (JWT)
  - *Open standard (RFC 7519)*
  - *Mechanism to securely transmit information between parties as a JSON object.*
  - *Can be **verified** and **trusted** as it is **digitally signed**.*
- Basic concepts
  - *Compact*
    - *→ has a small size*
    - *→ can be transmitted via a URL, POST, HTTP header.*
  - *Self-contained*
    - *→ payload contains all required user information.*

Use of JWT

- Authentication
  - *After user logs in, all following requests contain JWT token.*
  - *Single Sign On widely uses JWT nowadays*
- Information Exchange
  - *Signature ensures senders are who they say they are.*
  - *Message integrity – signature calculated using the header and the payload.*

JWT Structure

`<header>.<payload>.<signature>`

- Header
  - *Contains two parts, the type of the token (JWT) and the hashing algorithm being used (e.g. HMAC, SHA256, RSA).*

```
{
  "alg": "HS256",
  "typ": "JWT"
}
```

- Payload
  - *Contains the claims, i.e. statements about an entity (e.g. user).*
  - *Can be registered, public and private*
  - *Registered and public should be defined in IANA JSON Web Token Registry*

```
{
  "sub": "1234567890",
  "name": "John Doe",
  "admin": true
}
```

JWT Structure (Cont.)

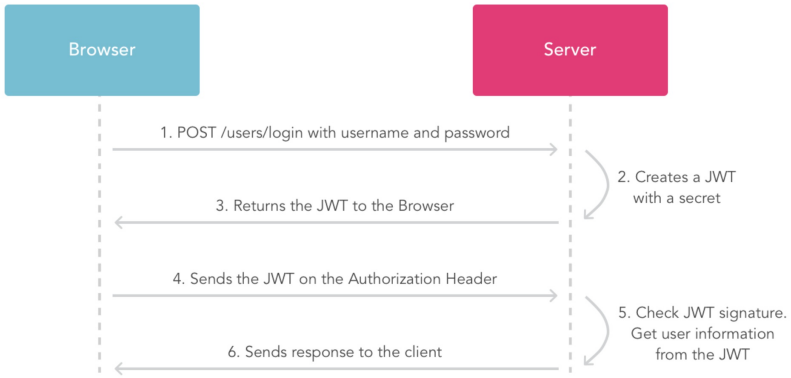
- Signature
  - *Signed encoded header, encoded payload and a secret.*
  - *For example, signature using HMAC SHA256 algorithm*

```
HMACSHA256(
    base64UrlEncode(header) + "." +
    base64UrlEncode(payload),
    secret)
```

- Example
  - *JWT is a three Base64-URL strings separated by dots*

```
eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.
eyJzdWIiOiIxMjM0NTY3ODkwIiwibmFtZSI6IkpvaG4
gRG9lIiwiaXNTb2NpYWwiOnRydWV9.
4pcPyMD09olPSyXnrXCjTwXyr4BsezdI1AVTmud2fU4
```

How to use JWT



1. *User sends username and password*
2. *Server verifies user, creates JWT token with a secret and a expiration time*
3. *Server sends JWT token back to the Browser*
4. *Browser sends JWT token on subsequent interations*

Notes

→ *Authorization header does not behave the same as cookies!*

→ *JWT should not contain secrets (passwords) as it can be read (on the client or if non-https connection is used)*

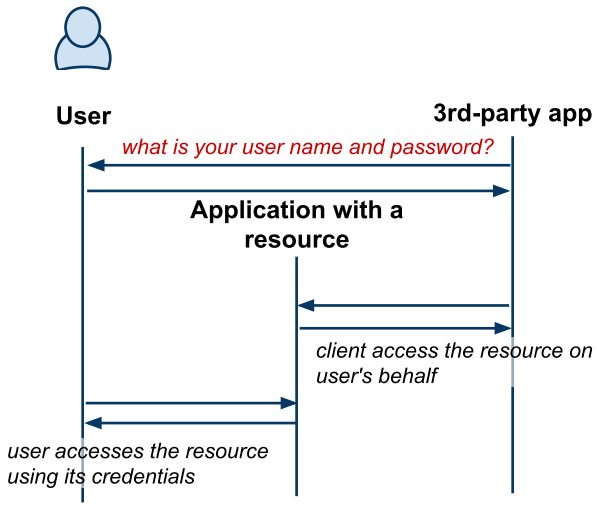
Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
  - *Client-side Web Apps*
  - *Server-side Web Apps*
  - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

Motivation

- Cloud Computing – Software as a Service
  - *Users utilize apps in clouds*
    - *→ they access **resources** via Web browsers*
    - *→ they store their data in the cloud*
    - *→ Google Docs, PicasaWeb, etc.*
  - *The trend is that SaaS are open*
    - *→ can be extended by 3rd-party developers through APIs*
    - *→ attract more users ⇒ increases value of apps*
  - *Apps extensions need to have an access to users' data*
- Need for a new mechanism to access resources
  - ***Users can grant access to third-party apps without exposing their users' credentials***

When there is no OAuth



- Users must share their credentials with the 3rd-party app
- Users cannot control what and how long the app can access resources
- Users must trust the app
  - *In case of misuse, users can only change their passwords*

OAuth 2.0 Protocol

- OAuth Objectives
  - *users can grant access to third-party applications*
  - *users can revoke access any time*
  - *supports:*
    - → *client-side web apps (implicit grant),*
    - → *server-side apps (authorization code), and*
    - → *native (desktop) apps (authorization code)*
- History
  - *Initiated by Google, Twitter, Yahoo!*
  - *Different, non-standard protocols first: ClientLogin, AuthSub*
  - *OAuth 1.0 – first standard, security problems, quite complex*
  - *OAuth 2.0 – new version, not backward compatibile with 1.0*
- Specifications and adoption
  - *OAuth 2.0 Protocol*
  - *OAuth 2.0 Google Support*

Terminology

- **Client**
  - *a third-party app accessing resources owned by* ***resource owner***
- **Resource Owner** (also user)
  - *a person that owns a resource stored in the* ***resource server***
- **Authorization and Token Endpoints**
  - *endpoints provided by an* ***authorization server*** *through which a* ***resource owner*** *authorizes requests.*
- **Resource Server**
  - *an app that stores resources owned by a* ***resource owner*** *(e.g., pictures in Google PicasaWeb)*
- **Authorization Code**
  - *a code that a* ***client*** *uses to request* ***access tokens*** *to access resources*
- **Access Token**
  - *a code that a* ***client*** *uses to access resources*

Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
  - *Client-side Web Apps*
  - *Server-side Web Apps*
  - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

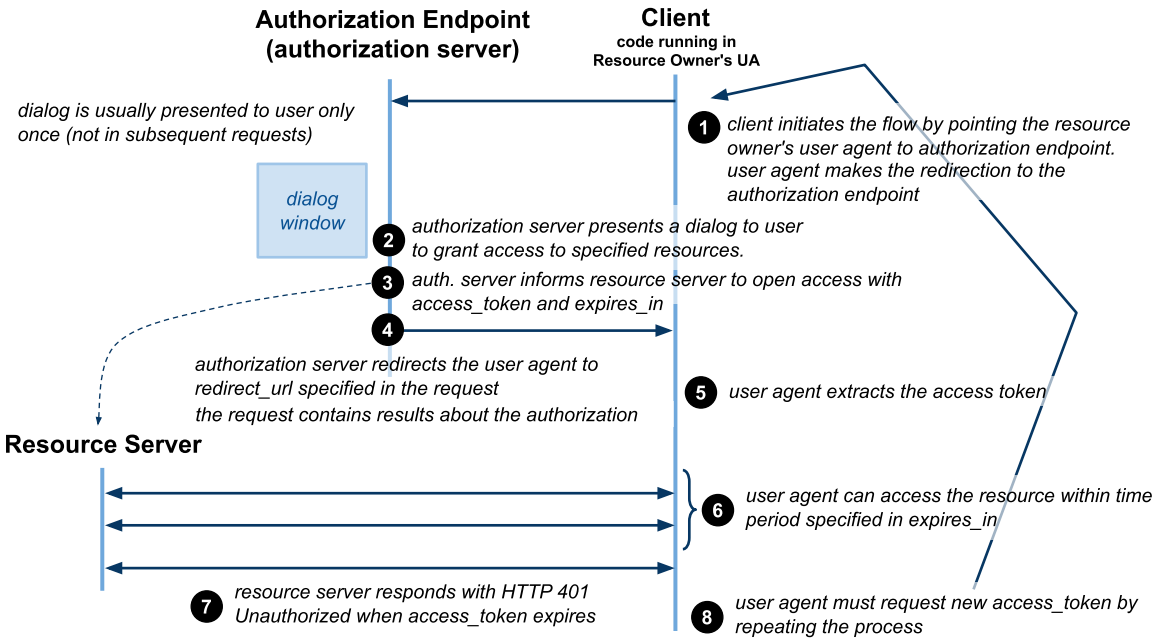
Client-side Web Apps

- Simplified version of OAuth 2.0 protocol
  - *JavaScript/AJAX apps running in a browser*
  - *Apps that cannot easily "remember" app state*
  - *limited number of interactions*
- Architecture
  - *User-agent processes a javascript/HTML code from the client*
  - *No need of authorization code*
- Basic Steps
  - *A client redirects a user agent to the authorization endpoint*
  - *A resource owner grants an access to the client or rejects the request*
  - *Authorization server provides an* `access_token` *to the client*
  - *Client access the resource with the* `access_token`
  - *When the token expires, client requests new token*

Demo – List of Contacts

- Display your Google contacts
  - *this demo requests authorization from you to access your Google contacts using client-side OAuth 2.0 protocol and then displays the contacts below. In order to transfer* `access_token` *from authorization window, it stores the* `access_token` *in a cookie.*
  - `access_token`
  - *Show contacts or revoke access*

Client-side Web Apps Protocol



Redirection – Step 1

- Methods and Parameters
  - *Methods:* `GET` *or* `POST`
  - *example authorazation endpoint url (Google):* `https://accounts.google.com/o/oauth2/auth`
  - *query string parameters or* `application/x-www-form-urlencoded`
    - → `client_id` *– id of the client that was previously registered*
    - → `redirect_uri` *– an URI that auth. server will redirect to when user grants/rejects*
    - → `scope` *– string identifying resources/services to be accessed*
    - → `response_type` *– type of the response (*`token` *or* `code`*)*
    - → `state` *(optional) – state between request and redirect*
  - *Example*

```
https://accounts.google.com/o/oauth2/auth?
client_id=621535099260.apps.googleusercontent.com&
redirect_uri=http://w20.vitvar.com/examples/oauth/callback.html&
scope=https://www.google.com/m8/feeds&
response_type=token
```

Callback – steps 4 and 5

- Resource owner grants the access
  - *authorization server calls back* `redirect_uri`
  - *client parses URL in JavaScript (Step 5)*
    - → *extracts* `access_token` *and* `expires_in` *(by using* `window.location.hash`*)*
  - *Example:*

```
http://w20.vitvar.com/examples/oauth/callback.html#
access_token=1/QbZfgDNsnd&
expires_in=4301
```

- Resource owner rejects the access
  - *authorization server calls back* `redirect_uri` *with query string parameter* `error=access_denied`
  - *Example:*

```
hhttp://w20.vitvar.com/examples/oauth/callback.html?
error=access_denied
```

Accessing Resources – Step 6

- Request
  - *client can access resources defined by* `scope`
  - *resources' URIs defined in a particular documentation*
  - *Example Google Contacts*
    - → *to access all users' contacts stored in Google*
    - → `scope` *is* `https://www.google.com/m8/feeds`
  - *Query string parameter* `oauth_token`

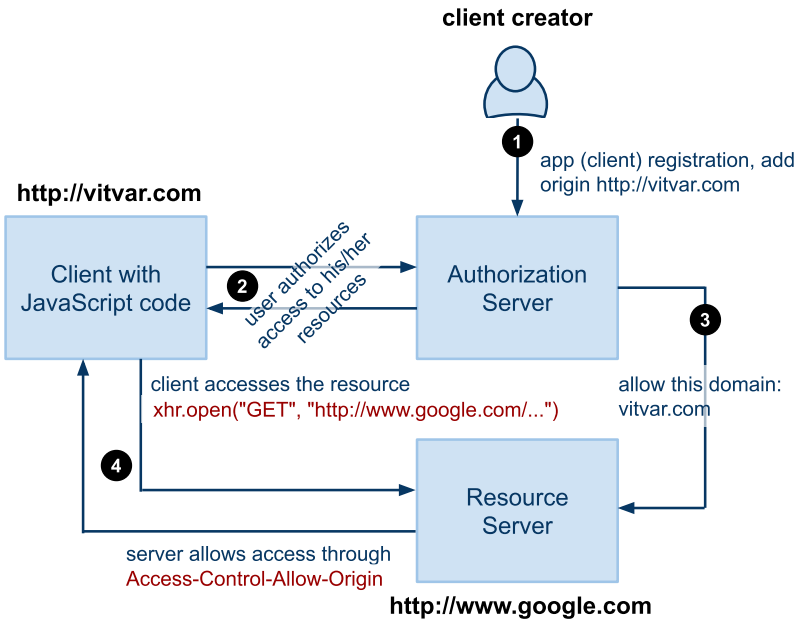
```
curl https://www.google.com/m8/feeds/contacts/default/full?
    oauth_token=1/dERFd34Sf
```

  - *HTTP Header* `Authorization`

```
curl -H "Authorization: OAuth 1/dERFd34Sf"
    https://www.google.com/m8/feeds/contacts/default/full
```

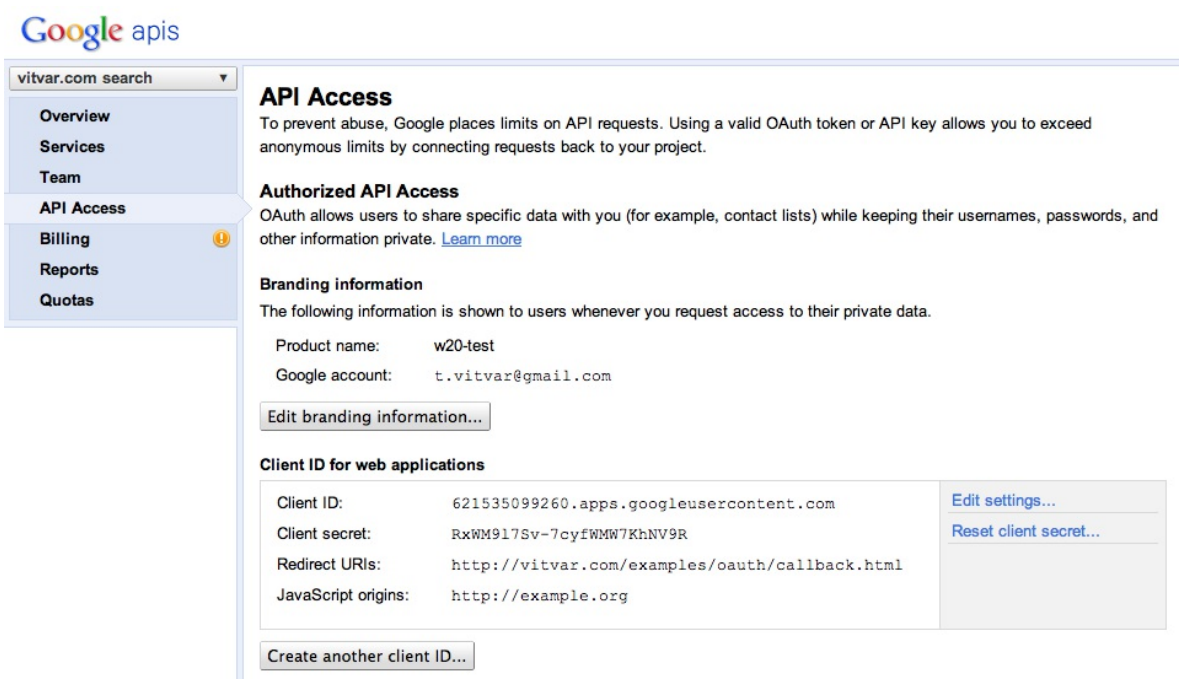
  - *The client can do any allowed operations on the resource*
- Response
  - *Success –* `200 OK`
  - *Error –* `401 Unauthorized` *when token expires or the client hasn't performed the authorization request.*

Cross-Origin Resource Sharing



- *see Same Origin and Cross-Origin for details*

Example Application Registration



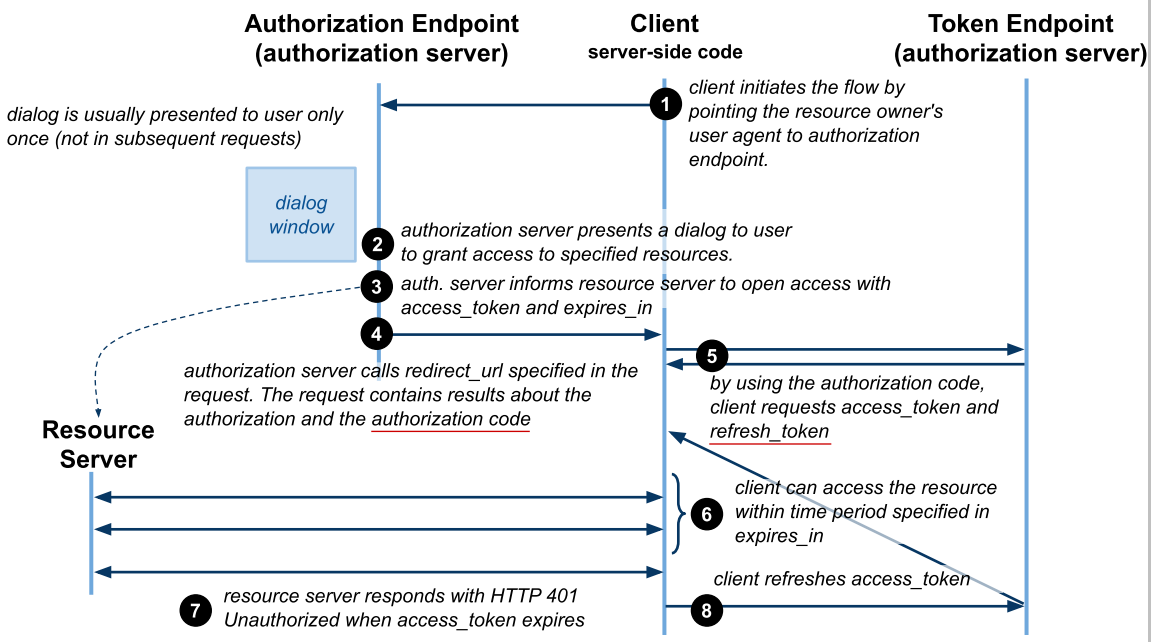
Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
  - *Client-side Web Apps*
  - *Server-side Web Apps*
  - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

Server-side Web Apps

- Additional interactions
  - *server-side code (any language), the app can maintain the state*
  - *additional interactions, authorization code*
- Architecture
  - *Client at a server requests, remembers and refresh access tokens*
- Basic steps
  - *Client redirects user agent to the authorization endpoint*
  - *Resource owner grants access to the client or rejects the request*
  - *Authorization server provides **authorization code** to the client*
  - *Client requests **access** and **refresh tokens** from the auth. server*
  - *Client access the resource with the access token*
  - *When the token expires, client refreshes a token with refresh token*
- Advantages
  - *Access tokens not visible to clients, they are stored at the server*
  - *more secure, clients need to authenticate before they can get tokens*

Server-side Web Apps Protocol



Redirection – Step 1

- Methods and Parameters
  - *same as for client-side app, except* `response_type` *must be* `code`
- Example

```
https://accounts.google.com/o/oauth2/auth?
client_id=621535099260.apps.googleusercontent.com&
redirect_uri=http://w20.vitvar.com/examples/oauth/callback.html&
scope=https://www.google.com/m8/feeds&
response_type=code
```

Callback + Access Token Request – steps 4, 5

- Callback
  - *authorization server calls back* `redirect_uri`
  - *client gets the* `code` *and requests* `access_token`
  - *example (resource owner grants access):*
    `http://w20.vitvar.com/examples/oauth/callback.html?code=4/P7...`
  - *when user rejects → same as client-side access*
- Access token request
  - `POST` *request to token endpoint*
    → example Google token endpoint:
    `https://accounts.google.com/o/oauth2/token`

```
POST /o/oauth2/token HTTP/1.1
Host: accounts.google.com
Content-Type: application/x-www-form-urlencoded

code=4/P7q7W91a-oMsCeLvIaQm6bTrgtp6&
client_id=621535099260.apps.googleusercontent.com&
client_secret=XTHhXh1S2UggvyWGwDk1EjXB&
redirect_uri=http://w20.vitvar.com/examples/oauth/callback.html&
grant_type=authorization_code
```

Access Token (cont.)

- Access token response
  - *Token endpoint responds with* `access_token` *and* `refresh_token`

```
{ "access_token"   : "1/fFAGRNJru1FTz70BzhT3Zg",
  "expires_in"     : 3920,
  "refresh_token"  : "1/6BMfW9j53gdGImsixUH6kU5RsR4zwI9lUVX-tqf8JXQ" }
```

- Refreshing a token
  - `POST` *request to the token endpoint with* `grant_type=refresh_token` *and the previously obtained value of* `refresh_token`

```
POST /o/oauth2/token HTTP/1.1
Host: accounts.google.com
Content-Type: application/x-www-form-urlencoded

client_id=21302922996.apps.googleusercontent.com&
client_secret=XTHhXh1SlUNgvyWGwDk1EjXB&
refresh_token=1/6BMfW9j53gdGImsixUH6kU5RsR4zwI9lUVX-tqf8JXQ&
grant_type=refresh_token
```

- Accessing a resource is the same as in the client-side app

Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
  - *Client-side Web Apps*
  - *Server-side Web Apps*
  - *OAuth 2.0 vs. OAuth 1.0*
- OpenID

Why new version?

- OAuth 1.0 in brief
  - *security not based on SSL*
  - *client must sign every request using a defined algorithm*
    → e.g., public-private key signatures by RSA
  - *More complex to be implemented by clients*
    → although client libraries exist
  - *not suitable for JavaScript-based clients*
- OAuth 2.0 simplifies the process
  - *SSL is required for all communications to generate the token*
  - *Signatures are not required for the actual API calls once the token has been generated*
    → SSL is also strongly recommended here
  - *supports various clients including JavaScript and mobile*

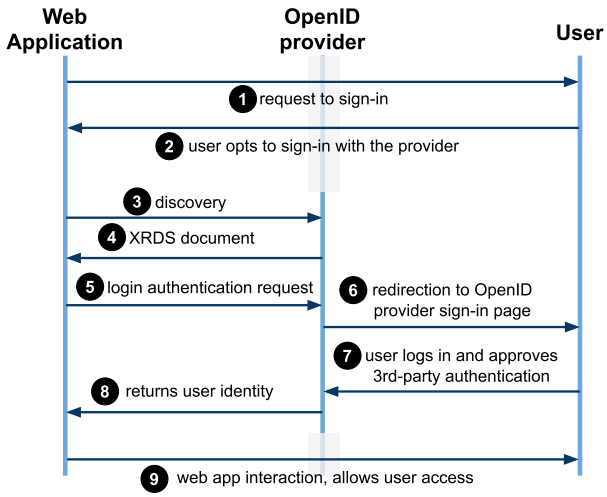
Overview

- Security Concepts
- Authentication and Authorization
- JSON Web Token
- OAuth 2.0
- OpenID

OpenID Protocol

- Motivation – many user accounts
  - *users need to maintain many accounts to access various services*
  - *multiple passwords problem*
- Objectives
  - *allows apps to utilize an OpenID provider*
    - *→ a third-party authentication service*
    - *→ federated login*
  - *users have one account with the OpenID provider and use it for apps that support the provider*
- OpenID providers
  - *it is a protocol, anybody can build a provider*
  - *Google, Yahoo!, Seznam.cz, etc.*
- Specification
  - *OpenID Protocol*

Interaction Sequence



- Discovery – discovery of a service associated with a resource
- XRDS – eXtensible Resource Descriptor Sequence
  - *format for discovery result*
  - *developed to serve resource discovery for OpenID*
  - *Web app retrieves endpoint to send login authentication requests*

Login Authentication Request – Step 5

- Example Google OpenID provider

```
https://www.google.com/accounts/o8/id
?openid.ns=http://specs.openid.net/auth/2.0
&openid.return_to=https://www.example.com/checkauth
&openid.realm=http://www.example.com/
&openid.assoc_handle=ABSmpf6DNMw
&openid.mode=checkid_setup
```

- Parameters
  - `ns` – *protocol version (obtained from the XRDS)*
  - `mode` – *type of message or additional semantics (*`checkid_setup` *indicates that interaction between the provider and the user is allowed during authentication)*
  - `return_to` – *callback page the provider sends the result*
  - `realm` – *domain the user will trust, consistent with* `return_to`
  - `assoc_handle` – *"log in" for web app with openid provider*

** Not all fields shown, check the OpenID spec for the full list of fields and their values*

Login Authentication Response – Step 8

- User logins successfully

```
http://www.example.com/checkauth
?openid.ns=http://specs.openid.net/auth/2.0
&openid.mode=id_res
&openid.return_to=http://www.example.com:8080/checkauth
&openid.assoc_handle=ABSmpf6DNMw
&openid.identity=https://www.google.com/accounts/o8/id/id=ACyQatiscWvwqs4UQV_l
```

  - *Web app will use* `identity` *to identify user in the application*
  - *response is also signed using a list of fields in the response (not shown in the listing)*

- User cancels

```
http://www.example.com/checkauth
?openid.mode=cancel
&openid.ns=http://specs.openid.net/auth/2.0
```

** Not all fields shown, check the OpenID spec for the full list of fields and their values*
