# Overview

- Developed from SPDY (2009) experimental protocol by Google
  - *May 2015: RFC 7540 (HTTP/2) and RFC 7541 (HPACK)*
  - *HTTP/2 standards extend (not replace) the previous HTTP standards*
- HTTP/1.x limitations
  - *HTTP/1.x clients need to use multiple connections to achieve concurrency*
  - *unnecessary network traffic – request and response headers not compressed*
  - *no effective resource prioritization*
- Primary goals
  - *Reduction of latency*
  - *enabling full request and response multiplexing*
  - *minimize protocol overhead via efficient compression of HTTP header fields*
  - *support for request prioritization and server push*
- HTTP/2 does not modify application semantics of HTTP
  - *HTTP methods, URIs, header fields are the same*
  - *HTTP/2 modifies **how data is formatted and transported** in communication*
- Literature and source
  - *I. Grigorik: High Performance Browser Networking, O'Reilly Media, Inc. 2013. ISBN: 9781449344757* 

# Binary Framing Layer

- Binary framing layer
  - *defines how HTTP messages are encapsulated and transferred*
  - *communication is split into messages and frames in binary format*

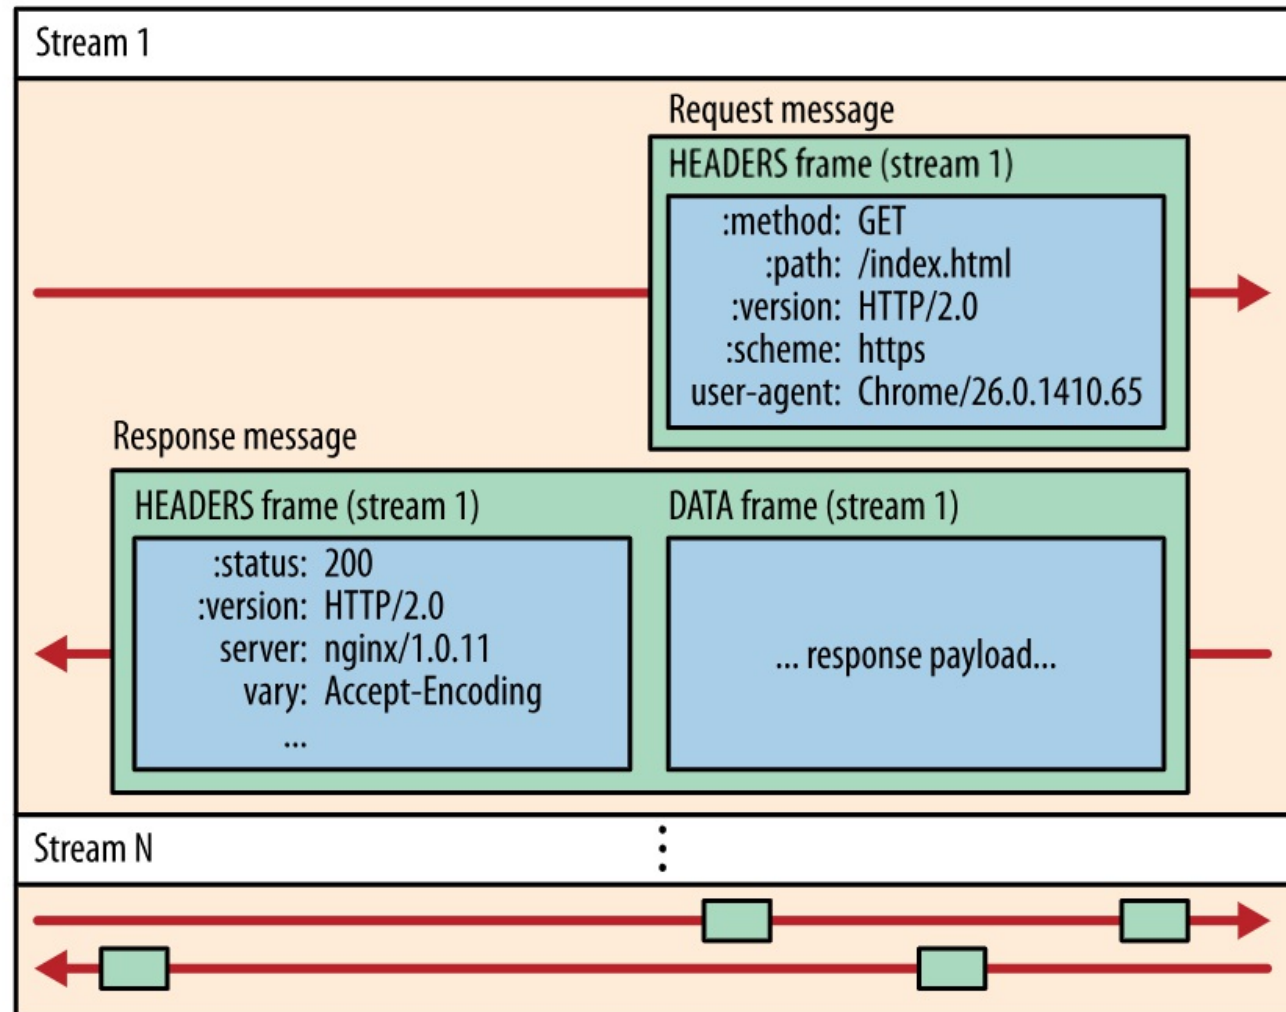

# HTTP/2 Communication

- Data exchange between the client and server
  - *break down of the communication into frames*
  - *frames are mapped to messages that belong to a particular stream*
  - *communication is **multiplexed within a single TCP connection**.*
- Stream
  - *bi-directional flow of bytes in a connection*
  - *may carry one or more messages*
  - *may have a priority*
- Message
  - *a sequence of frames*
  - *it maps to logical request or response message*
- Frame
  - *the smallest unit of communication*
  - *each has a frame header which identifies a stream to which it belongs.*

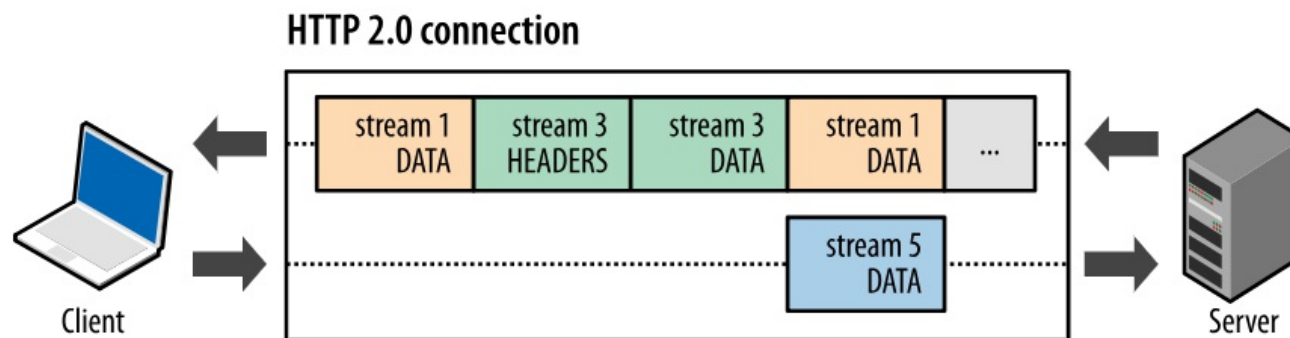

# Streams, messages, and frames

Connection

# Request and response multiplexing

- Parallel requests
  - *HTTP/1.x can use HTTP pipelining; they open multiple connections*
    - *browser typically opens up six connections*
  - *HTTP/2 allows full request and response multiplexing*
    - *Allows for parallel in-flight streams*

- Performance benefits
  - *Interleave requests/responses in parallel without blocking any one.*
  - *Deliver lower page load times by eliminating unnecessary latency*
  - *Improve utilization of available network capacity*

# HTTP/1.x Optimization

## non-persistent

## persistent

## pipelining

# One connection

- Multiplexing allows for:
  - *all connections are persisted*
  - *only one connection required per origin*
- Advantages
  - *significant reduction of the overall protocol overhead*
  - *use of fewer connections reduces the memory and processing footprint along the full connection path (client, intermediaries, origin servers)*
  - *reduces operational costs and improves network capacity*
  - *Improves performance of HTTPS deployments*
    - *fewer expensive TLS handshakes*
    - *better session reuse*
    - *overall reduction in required client and server resources*

# Flow control

- Prevent sender from receiving data it does not want
  - *Receiver is busy or under heavy load*
  - *Receiver can allocate fixed amount of resources for particular stream*
- Examples
  - *Client request a video stream; a user pauses the stream*
    - *the client wants to pause the stream delivery to avoid buffering*
  - *A proxy server has a fast downstream and slow upstream*
    - *the proxy server can control how quickly the downstream delivers data to match the speed of upstream*
    - *better control of resource usage*
  - *Similar problems as in TCP control*
- Flow control
  - *Sender and receiver both advertise stream flow control window in bytes*
    - = *the size of the available buffer space to hold the incoming data*
  - *exchanged by special SETTINGS and WINDOW\_UPDATE frames*
  - *Flow control is hop-by-hop, not end-to-end*
    - *an intermediary can set its own flow control*

# Server push

- Ability to send multiple responses for a single request
  - *A response to the request is sent back*
  - *Additional resources can be pushed without client requesting them*
  - *Hypertext – "server knows what the client will need"*

- Similar to resource inlining
  - *A resource is pushed to the client in HTML/CSS resource*
- Performance benefits
  - *Cached by the client, reused across pages, multiplexed, declined by the client*

# Push promise

- **PUSH\_PROMISE** frames
  - A signal that the server intends to push resources to the client
  - The client needs to know which resources the server intends to push to avoid creating duplicate requests for these resources.
- After the client receives **PUSH\_PROMISE**
  - it may decline the stream (via **RST\_STREAM** frame)
    - For example, when the resource is already in the cache
    - As for inline resources, this is not possible, the client always receives them
  - it can limit the number of concurrently pushed streams
  - it can adjust the initial flow control window to control how much data is pushed when the stream is first opened
  - it can disable server push entirely
- pushed resources must obey the same-origin policy

# Stream Prioritization

- Purpose
  - Messages split into **frames** which are delivered in multiplexed **streams**
  - The order in which frames are delivered is important for a good performance
  - Client can define stream prioritization
    - optimizations in the browser, change prioritization based on user interaction
- Streams' weights and dependency
  - Each stream can be assigned an integer weight between 1 and 256.
  - Each stream may be given an explicit dependency on another stream.

# Stream Prioritization (cont.)

- Dependency
  - *referencing the unique identifier of another stream as its parent*
  - *if the identifier is omitted the stream is dependent on the "root stream"*
  - *The parent stream should be allocated resources ahead of its dependencies.*
    - *"Please process and deliver response D before response C"*
- Weights
  - *Sibling streams have resources allocated as per their weights*
  - *Example*
    - *Sum all the weights:  $4 + 12 = 16$*
    - *Divide each stream weight by the total weight:  $A = 12/16$ ,  $B = 4/16$*
    - *Stream A receives  $3/4$  and stream B receives  $1/4$  of available resources;*

# Header compression

- Purpose
  - Each HTTP request/response contains a set of headers (metadata)
  - HTTP/1.x – metadata sent as plain text, adds 500-800 bytes per transfer
- HTTP/2 provides
  - Request and response metadata are compressed using HPACK format
    - header fields encoded via a static Huffman code – reduces size
    - client and server maintain an **indexed list of previously seen header fields**
