- Introduction
- Cloud Architecture
- Infrastructure as a Service

Terminology

- Cloud computing
- *aaS
- DevOps
- Cloud Native, Microservices
- Serverless

What is a Cloud?

A different way of thinking

- Got your grand mum's savings under your pillow?
 - → probably not, you better have them in your bank
- Data is your major asset
- you better have them in a "bank" too
- Someone can abuse your data?
- banks bankrupt too, sometimes it is a risk you take
- there is a market and a competition

Outsourcing of application infrastructure

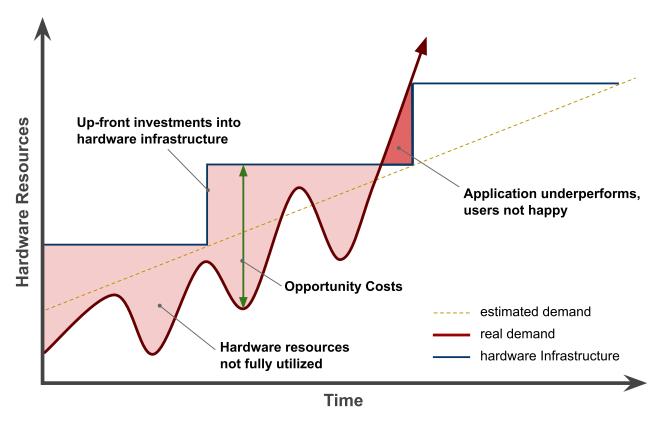

- Reliability and availability
- Low costs pay-per-use
- Elasticity can dynamically grow with your apps
- CAPEX vs. OPEX

What is a Cloud?

- Any app you access over the web?
- A datacenter?
 - Offers virtualization
 - Any company having a datacenter wants to move to
- Cloud provider should also offer services, such as:
 - scalability, storage
 - Possible to configure programmatically
 - → integration to enterprise administration processes
 - → usually REST interface

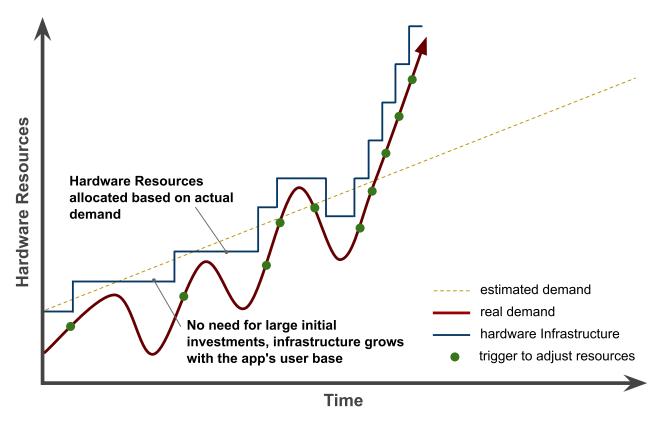

Traditional Solution to Infrastructure

- Traditional hardware model
 - *Up-front hardware investments*
 - Hardware not optimally utilized

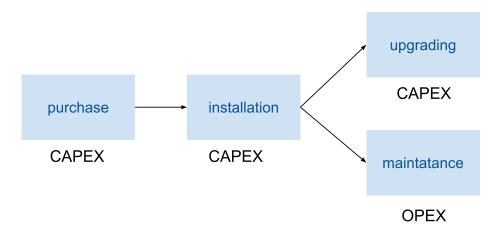

Good Performance – Cloud Solution

- Cloud Computing model
 - No up-front hardware investments
 - Hardware optimally utilized

CAPEX vs. OPEX

- Captial expenditure/capital expense (CAPEX)
 - money to spend to buy, maintain or improve fixed assets
 - → buildings, vehicels, equipment or land
 - have impact on costs vs. profit and tax

- Operational expenditure (OPEX)
 - ongoing costs for running a product, business, or systems
 - *OPEX* are entirely tax-deductible
- Cloud lets you trade CAPEX for OPEX
 - No investments in data centers and infrastructures
 - You pay only when you consume resources

Cloud Computing Concepts

On-demand and self-service

- Resources are provisioned as they are requested and when they are required
- No human interaction, automatic

Broad network access

- Capabilities are available over the network

Resource pooling

- Provider's computing resources reused by multiple tenants (multitenancy)
- Resourcces are dynamically assigned/re-assigned according to demand
- Computing resources: CPU, memory, storage, network

Scalability and elasticity

- Infrastructure may grow and shrink according to needs
- Automatic or manual

Measured service

- Resource usage can be monitored, controlled and reported

• Pay-per-use

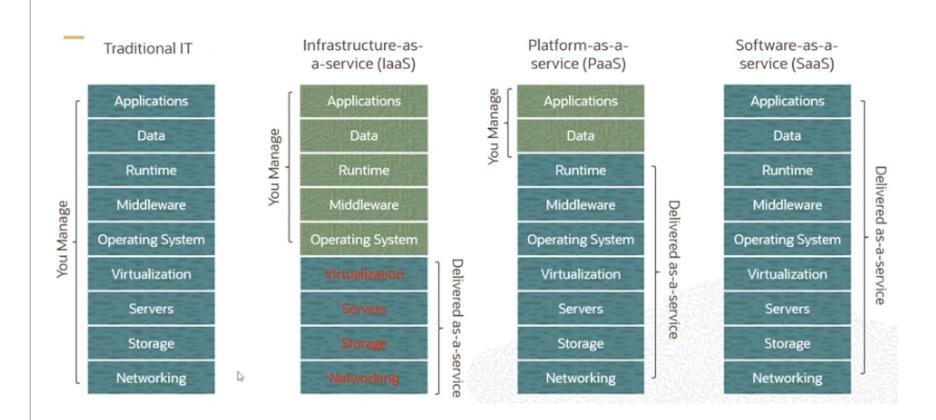

- Consumers only pay for resources when they use them

Cloud Computing Concepts (Cont.)

- Service Models (aka Cloud Layers)
 - IaaS Infrastructure as a Service
 - PaaS Platform as a Service, Serverless
 - \rightarrow MWaaS, DBaaS, ...
 - \rightarrow FaaS
 - SaaS Software as a Service
- Deployment Models
 - Public Cloud
 - Private Cloud
 - Hybrid Cloud

- Introduction
- Cloud Architecture
 - Service Models
 - Multitenancy
- Infrastructure as a Service

Service Models

IaaS: Infrastructure as a Service

Usage

- Predefined shapes of compute instances (e.g. micro, small, large, extra-large)
 - → for example: RedHat 7.8, 613 MB of memory, 1 TB block storage
- Pay-per-use pay for resources you use (time or amount)
 - → no up-front costs

• IaaS Services Examples

- Load balancer
- Autoscaling
- Connectivity with on-premise network
- Resource monitoring

IaaS providers

- Amazon EC2, GoGrid, Rackspace, OpenNebula, Google Cloud, Oracle OCI, ...

PaaS: Platform as a Service

Usage

- Choose software platform, e.g., JEE, .NET, Python, etc.
- Pay-per-use pay for the resources you use; no up-front costs
- Cloud native, microservices, containers

• PaaS features

- Serverless
- Auto Scalling and Load balancing
- Local development environment
- Administration API

PaaS providers

- Google App Engine first PaaS service
- Today, mostly Kubernetes, Google, Heroku, Azure, AWS, Oracle

SaaS: Software as a Service

- Software delivery model for applications hosted in the cloud
 - typically software for end-users
 - services accessed using a web browser
 - provides API for programmatic access
- SaaS characteristics
 - Typically build on top of IaaS or PaaS
 - Configurable and customizable modern Web applications
 - Usually basic version for free, need to pay for "pro" version
 - Global availability any computer, any device
 - Easy management automatic and fast updates
 - − Pay-per-use − pay for the time you use
- SaaS providers
 - Google Apps, Salesforce, ...

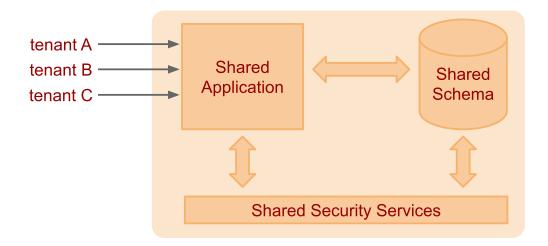

- Introduction
- Cloud Architecture
 - Service Models
 - Multitenancy
- Infrastructure as a Service

Multitenancy

- Architectural approach where resources are shared between multiple tenants or consumers
- Implications
 - Centralization of infrastructure in locations with lower costs
 - Peak-load capacity increases
 - Utilisation and efficiency improvements for systems that are not well utilised
- Sharing options
 - Shared Everything
 - Shared Infrastructure
 - → Virtual Machines
 - → OS "virtualization"

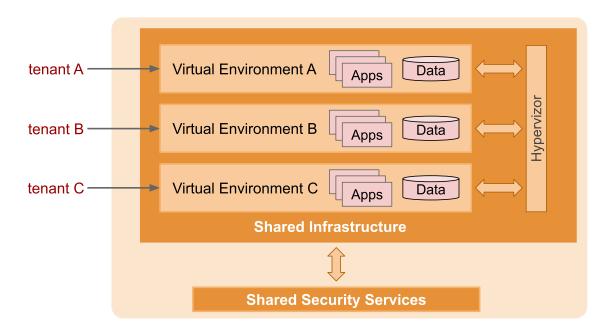

Shared Everything

- Resources are shared between all tenants or consumers
 - tenant: a service consumer
- Common for the SaaS model
- The application should provide tenant isolation
- Data for multiple tenants is stored in the same database tables

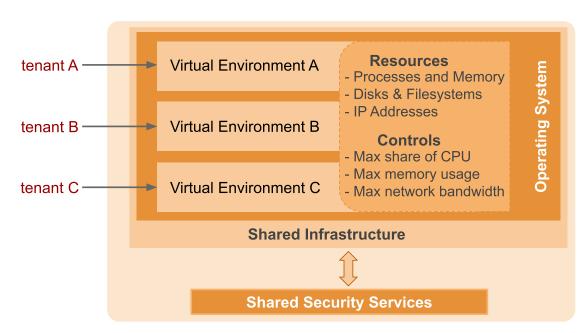

Shared Infrastructure: Virtual Machines

- Infrastructure shared via virtual machines
 - each tenant has its own virtual environment
 - Isolation provided by hypervisor
 - → hypervisor: virtual machine manager, runs virtual machines
 - Resource contention depends on VM capability and configuration
 - Adds an additional layer and processes to run and manage

Shared Infrastructure: OS Virtualization

- Infrastructure shared via OS Virtualization
 - Each tenant has its own processing zone
 - Isolation provided by the operating system
 - Resource contention depends on zone configuration
 - No VMs to run and manage, no abstraction layer between app & OS

- Introduction
- Cloud Architecture
- Infrastructure as a Service
 - Networking
 - Compute
 - Storage
 - Infrastructure as Code

- Infrastructure = environment where your app is running
- Tenancy = your "space" in the cloud
- What you need
 - Servers (compute instances) to run your app in a location (region)
 - Connectivity
 - → Private network for intra-communication
 - → Public network for internet communication
 - → Firewall (security) rules
 - \rightarrow Route tables
 - Storage
 - → *Operating system*
 - \rightarrow Your app data
 - Identity Management
 - → Who and how can access and control your tenancy
 - Monitoring, Logging, Auditing

Region

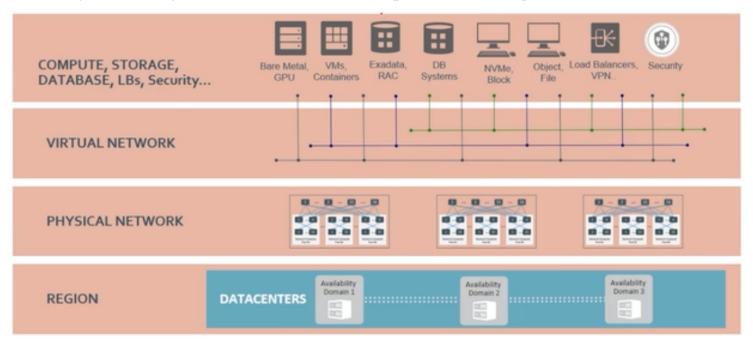

• Region = location on a planet where cloud data centers are located

- Why location matters...
 - Latency your users should be close to your app
 - Regulations your data should be stored in EU
 - Connectivity to external providers
 - \rightarrow Such as other cloud vendors

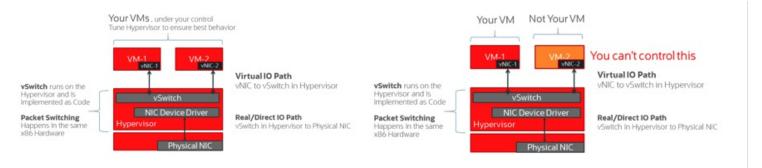

Datacenters

- Datacenter (aka Availability Domain AD)
 - Computing resources in a location within a region
 - One or more datacenters exsit in a region
 - → They are completely de-correlated, independent
 - → They have separated power supply, do not share underlying infrastructure
 - \rightarrow If one DC fails, the other one is up and running

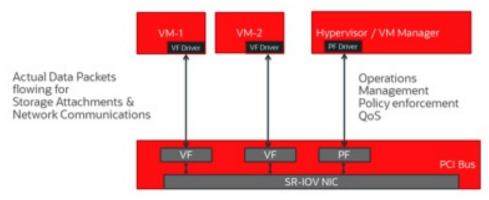

Off-box Network Virtualization

- Gen 1.0 Cloud, inefficient Resource Sharing
 - On-Premise virtualization to share resources amongst multiple tenants in the cloud.

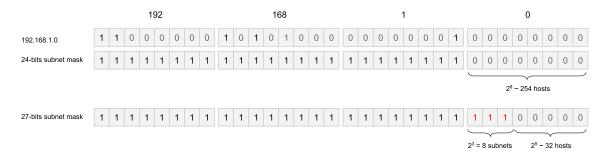

- Gen 2.0 Cloud
 - Smart-NIC accelerated SR-IOV (Single Root I/O Virtualization)
 - → Networking is a specialized function, needs hardware/sillicon to accelerate it

- Introduction
- Cloud Architecture
- Infrastructure as a Service
 - Networking
 - Compute
 - Storage
 - Infrastructure as Code

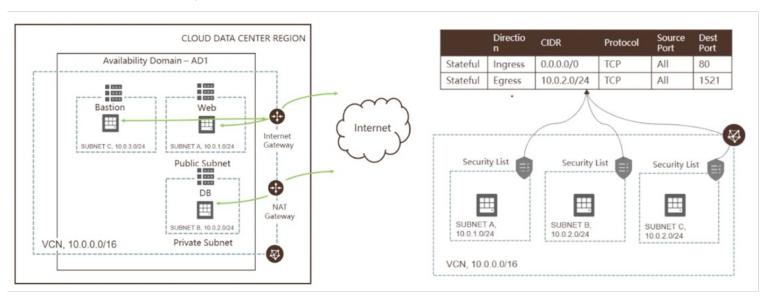

Virtual Cloud Network

- VCN = a private network in a **single region** in which your instances reside
- A a single and contigous IPV4 CIDR block of your choice
 - CIDR (classless inter-domain routing) notation
 - IP address:
 - → network prefix (the most significant bits) and
 - → interfaces on the network (least significant bits) ~ network hosts
 - *Example:* 192.168.1.0/24
 - \rightarrow *IP range:* 192.168.1.0 192.168.1.255
- You further create subnets on a VCN to organize your instances
 - The subnets must be "within" the VCN, they can span across ADs
 - Example: using 27 bits for a subnet mask allow for 8 subnets
 - \rightarrow 192.168.1.0/27, 192.168.1.32/27, 192.168.1.64/27, ...
 - → Each subnet can have 32 hosts

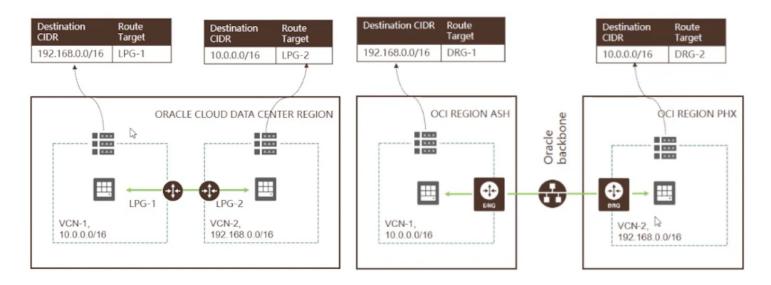

VCN Routing and Security

- Private and Public subnets
 - Public can communicate in/out from/to Internet
 - Internet traffic routed to public subnet
 - Private can be completely isolated or communicate to Internet only
- Route tables
 - Required to route across subnets and in/out from the Internet
- Security
 - Control access to/from the subnet

Peering

- Local Peering
 - Connecting two VCNs in a region
- Remote Peering
 - Connecting two VCNs across regions
- Connectivity with on-premise datacenter
 - Fast connection needs to be in place
 - Secure VPN needs to be established

- Introduction
- Cloud Architecture
- Infrastructure as a Service
 - Networking
 - Compute
 - Storage
 - Infrastructure as Code

Compute Instances

- Shape = amount of memory and CPU an instance is using
 - There are classes of shapes that you can choose from
 - Standard and HPC/GPU shapes
- Virtual Machine (VM) multi-tenant model
 - A hypervisor to virtualize the underlying Bare Metal server into smaller VMs
- Bare Metal (BM) single-tenant model
 - Direct hardware access, full bare metal server
 - Types of workloads: performance intensive, require a specific hypervisor
- Dedicated VM Hosts (DVM) single-tenant model
 - VM instances running on dedicated single-tenant servers
 - *Not shared with other customers*

- States: start, stop, reboot, terminate
 - Billing pauses in STOP state but depends on shape

Image

- Image
 - A template of a virtual hard drive with OS
 - Other software, libraries, configurations, etc.
- Stored on a boot volume
- Base images are provided
 - CentOS, Ubuntu, Windows Server, Oracle Linux, RedHat, etc.
 - Some may require licence costs
- Custom images
 - You can create a custom image from the base image
 - Specific packages, libraries or custom configuiration
 - You store the image in the object storage

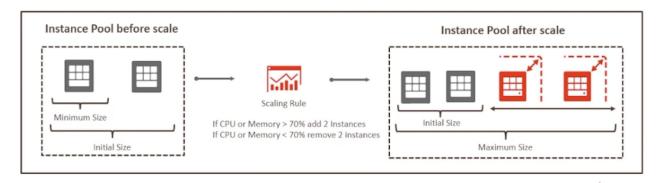

Autoscaling

- Instance configuration
 - OS image, metadata, shape, vNICs, storage, subnets
 - Apply configuration to multiple instances at the same time
 - → You can manage them all together (start, stop, terminate)

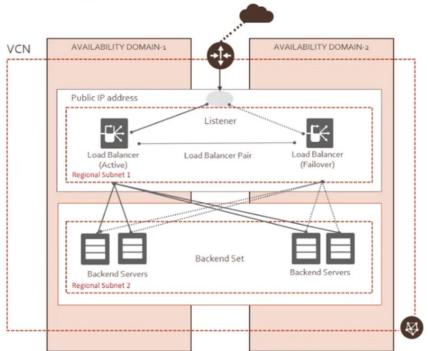

Autoscaling

- Automatically adjust a number of compute instances in an instance pool
- Control using performance metrics such CPU or memory utilization
- cooldown period time between scale in and scale out (e.g. 300 seconds)

Load Balancer

- Managed service
 - Health check checks health status of backends (TCP, HTTP)
 - Algorithm round-robin, IP hash, least connections
- Supports protocols
 - TCP, HTTP 1.1, HTTP/2, WebSocket, SSL termination, end-to-end SSL
 - Supports sticky sessions (sessions persistence)
- High Availability
 - Primary and stand-by LB
 - Each LB is in different AD
 - Failover uses floating IP

- Introduction
- Cloud Architecture
- Infrastructure as a Service
 - Networking
 - Compute
 - Storage
 - Infrastructure as Code

Object Storage

- Types of data to store
 - Storage for unstructured data (images, media files, logs, backups)
 - Data managed as objects, provides API using HTTP verbs
- Namespace
 - Logical entity that serves as top-level container for all bueckts and objects
 - Each tenancy is provided one unique namespace
- Bucket
 - A logical container for storing objects
 - Bucket names must be unique within tenancy
 - Hot bucket standard, can be accessed immediatelly
 - Cold bucket rarely accessed data, need to be restored
 - → Minimum retention, such as 90 days
 - → Time to First Byte (TTFB) is in hours, e.g. 4 hours
- Object and metadata
 - data managed as objects regardless data type
- Example object URL path:

/n/<namespace>/b/<bucket>/o/<object name>

Block Storage

Local NVMe SSD device

- Locally attached device, provided by some shapes, 200K IOPS 1M IOPS
- Workloads that require high storage performance
- usually no RAID, snapshots, backups

Block volumes

- Reside in storage servers
- NVMe SSD based, up to 35K IOPS
- Data stored on block volumes beyond the lifespan of compute instance
- Multiple replicas across multiple storage servers

• File Storage

- Network file server (NFS)
- Client mounts a mount target (NFS endpoint) and an export path
- Example

sudo mount 10.0.0.6/example1/path /mnt/mountpointA

- Introduction
- Cloud Architecture
- Infrastructure as a Service
 - Networking
 - Compute
 - Storage
 - Infrastructure as Code

- Definition
 - Application envs (in a cloud) managed via definition files
 - Version control, team development, scripting, etc.
- Major Technologies
 - Configuration Management Tools
 - → install and manage software on machines that already exist
 - → Examples: Ansible, Chef, Puppet
 - Abstraction of cloud infrastructure
 - \rightarrow Terraform

Terraform

- Higher-level abstraction of the datacenter and associated services
- Supports many service providers
 - Google, Microsoft, Oracle, AWS
- Steps
 - 1. Description of resources in Hashicorp Configuration Language (HCL)
 - instances, networks, firewall rules, routing tables, etc.
 - 2. Terraform generates execution plan to reach the desired state
 - 3. Terraform executes the plan to reach the desired state; can generate incremental execution plan
