Czech Technical University in Prague
Faculty of Information Technologies • Software and Web Engineering • https://vitvar.com/lectures

- Introduction
- Cloud Architecture
- Infrastructure as a Service

# **Terminology**

- Cloud computing
- \*aaS
- DevOps
- Cloud Native, Microservices
- Serverless

# What is a Cloud?

# A different way of thinking

- Got your grand mum's savings under your pillow?
  - → probably not, you better have them in your bank
- Data is your major asset
- you better have them in a "bank" too
- Someone can abuse your data?
- banks bankrupt too, sometimes it is a risk you take
- there is a market and a competition

# Outsourcing of application infrastructure

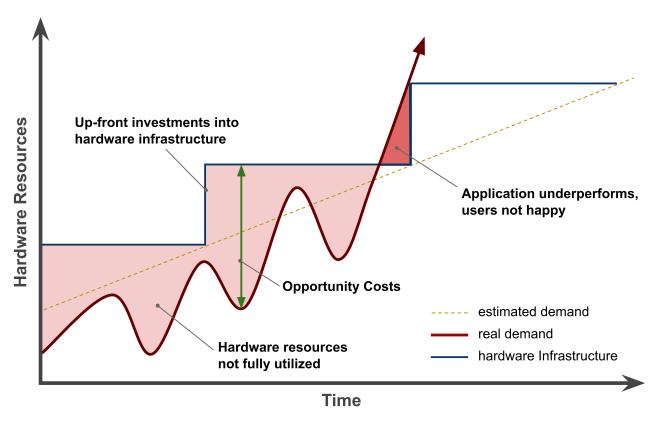

- Reliability and availability
- − Low costs − pay-per-use
- Elasticity can dynamically grow with your apps
- CAPEX vs. OPEX

### What is a Cloud?

- Any app you access over the web?
- A datacenter?
  - Offers virtualization
  - Any company having a datacenter wants to move to
- Cloud provider should also offer services, such as:
  - scalability, storage
  - Possible to configure programmatically
    - → integration to enterprise administration processes
    - → usually REST interface

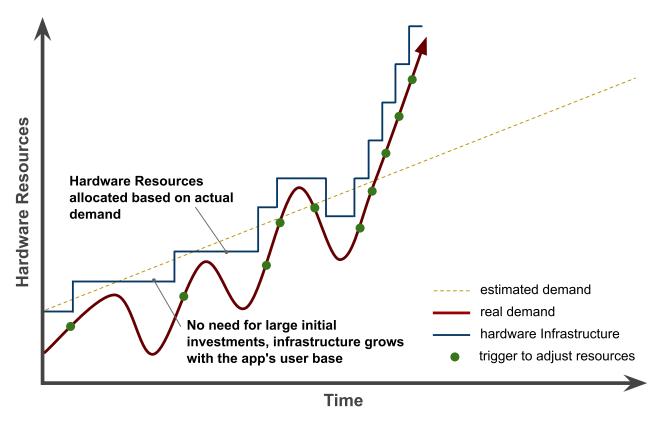

# **Traditional Solution to Infrastructure**

- Traditional hardware model
  - *Up-front hardware investments*
  - Hardware not optimally utilized

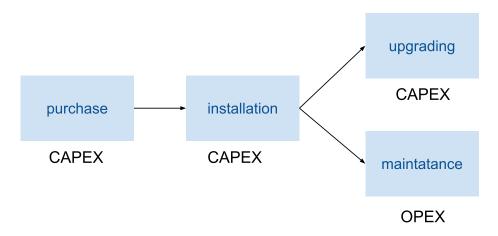

# **Good Performance – Cloud Solution**

- Cloud Computing model
  - No up-front hardware investments
  - Hardware optimally utilized

### CAPEX vs. OPEX

- Captial expenditure/capital expense (CAPEX)
  - money to spend to buy, maintain or improve fixed assets
    - → buildings, vehicels, equipment or land
  - have impact on costs vs. profit and tax

- Operational expenditure (OPEX)
  - ongoing costs for running a product, business, or systems
  - *OPEX* are entirely tax-deductible
- Cloud lets you trade CAPEX for OPEX
  - No investments in data centers and infrastructures
  - You pay only when you consume resources

# **Cloud Computing Concepts**

#### On-demand and self-service

- Resources are provisioned as they are requested and when they are required
- No human interaction, automatic

#### Board network access

- Capabilities are available over the network

#### Resource pooling

- Provider's computing resources reused by multiple tenants (multitenancy)
- Resourcces are dynamically assigned/re-assigned according to demand
- Computing resources: CPU, memory, storage, network

### Scalability and elasticity

- Infrastructure may grow and shrink according to needs
- Automatic or manual

#### Measured service

- Resource usage can be monitored, controlled and reported

#### • Pay-per-use

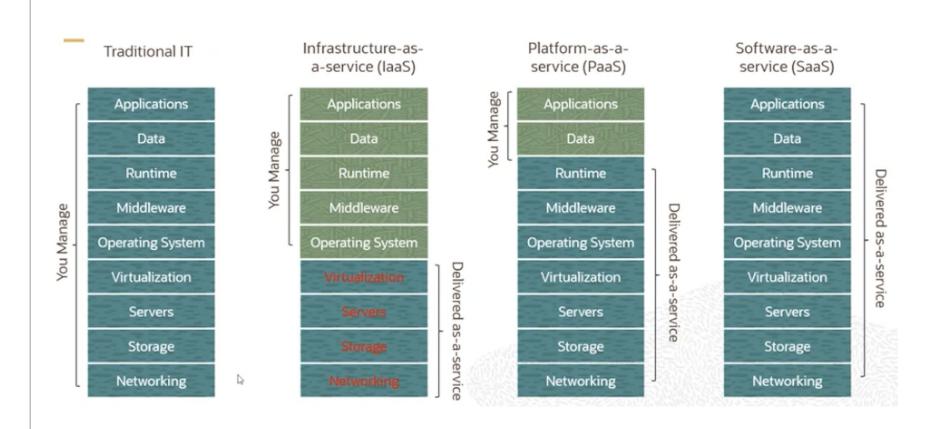

- Consumers only pay for resources when they use them

# **Cloud Computing Concepts (Cont.)**

- Service Models (aka Cloud Layers)
  - IaaS Infrastructure as a Service
  - PaaS Platform as a Service, Serverless
    - $\rightarrow$  MWaaS, DBaaS, ...
    - $\rightarrow$  FaaS
  - SaaS Software as a Service
- Deployment Models
  - Public Cloud
  - Private Cloud
  - Hybrid Cloud

- Introduction
- Cloud Architecture
  - Service Models
  - Multitenancy
- Infrastructure as a Service

# **Service Models**

# IaaS: Infrastructure as a Service

#### Usage

- Predefined shapes of compute instances (e.g. micro, small, large, extra-large)
  - → for example: RedHat 7.8, 613 MB of memory, 1 TB block storage
- Pay-per-use pay for resources you use (time or amount)
  - → no up-front costs

### • IaaS Services Examples

- Load balancer
- Autoscaling
- Connectivity with on-premise network
- Resource monitoring

#### IaaS providers

- Amazon EC2, GoGrid, Rackspace, OpenNebula, Google Cloud, Oracle OCI, ...

# PaaS: Platform as a Service

### Usage

- Choose software platform, e.g., JEE, .NET, Python, etc.
- Pay-per-use pay for the resources you use; no up-front costs
- Cloud native, microservices, containers

#### • PaaS features

- Serverless
- Auto Scalling and Load balancing
- Local development environment
- Administration API

### PaaS providers

- Google App Engine first PaaS service
- Today, mostly Kubernetes, Google, Heroku, Azure, AWS, Oracle

# SaaS: Software as a Service

- Software delivery model for applications hosted in the cloud
  - typically software for end-users
  - services accessed using a web browser
  - provides API for programmatic access
- SaaS characteristics
  - Typically build on top of IaaS or PaaS
  - Configurable and customizable modern Web applications
  - Usually basic version for free, need to pay for "pro" version
  - Global availability any computer, any device
  - Easy management automatic and fast updates
  - − Pay-per-use − pay for the time you use
- SaaS providers
  - Google Apps, Salesforce, ...

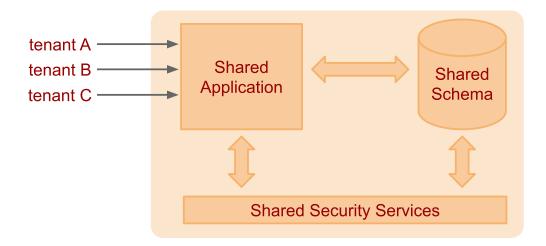

- Introduction
- Cloud Architecture
  - Service Models
  - Multitenancy
- Infrastructure as a Service

# **Multitenancy**

- Architectural approach where resources are shared between multiple tenants or consumers
- Implications
  - Centralization of infrastructure in locations with lower costs
  - Peak-load capacity increases
  - Utilisation and efficiency improvements for systems that are not well utilised
- Sharing options
  - Shared Everything
  - Shared Infrastructure
    - → Virtual Machines
    - → OS "virtualization"

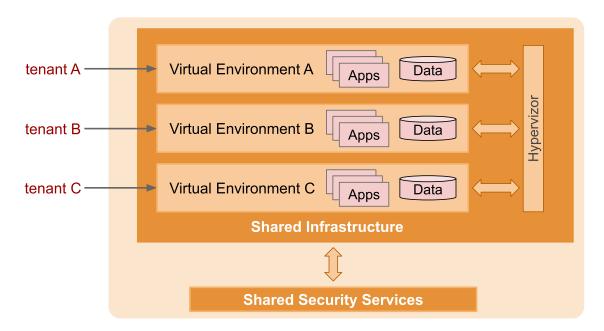

# **Shared Everything**

- Resources are shared between all tenants or consumers
  - tenant: a service consumer
- Common for the SaaS model
- The application should provide tenant isolation
- Data for multiple tenants is stored in the same database tables

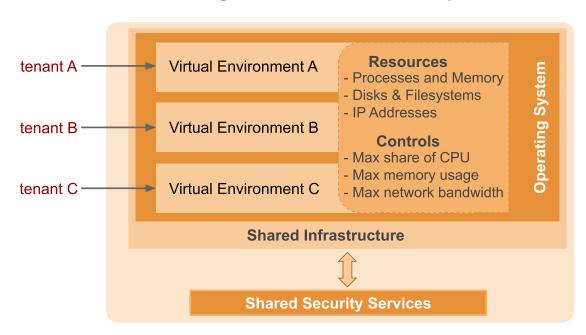

# **Shared Infrastructure: Virtual Machines**

- Infrastructure shared via virtual machines
  - each tenant has its own virtual environment
  - Isolation provided by hypervisor
    - → hypervisor: virtual machine manager, runs virtual machines
  - Resource contention depends on VM capability and configuration
  - Adds an additional layer and processes to run and manage

# **Shared Infrastructure: OS Virtualization**

- Infrastructure shared via OS Virtualization
  - Each tenant has its own processing zone
  - Isolation provided by the operating system
  - Resource contention depends on zone configuration
  - No VMs to run and manage, no abstraction layer between app & OS

- Introduction
- Cloud Architecture
- Infrastructure as a Service
  - Networking
  - Compute
  - Storage
  - Infrastructure as Code

- Infrastructure = environment where your app is running
- Tenancy = your "space" in the cloud
- What you need
  - Servers (compute instances) to run your app in a location (region)
  - Connectivity
    - → Private network for intra-communication
    - → Public network for internet communication
    - → Firewall (security) rules
    - $\rightarrow$  Route tables
  - Storage
    - → *Operating system*
    - $\rightarrow$  Your app data
  - Identity Management
    - → Who and how can access and control your tenancy
  - Monitoring, Logging, Auditing

# Region

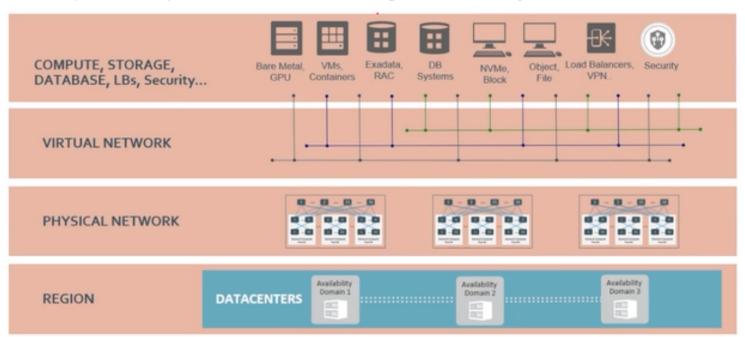

• Region = location on a planet where cloud data centers are located

- Why location matters...
  - Latency your users should be close to your app
  - Regulations your data should be stored in EU
  - Connectivity to external providers
    - $\rightarrow$  Such as other cloud vendors

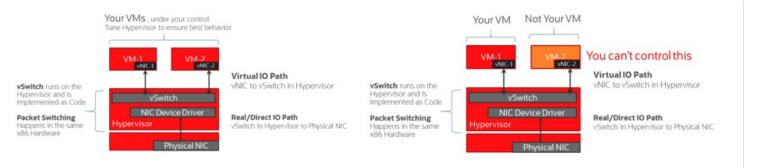

### **Datacenters**

- Datacenter (aka Availability Domain AD)
  - Computing resources in a location within a region
  - One or more datacenters exsit in a region
    - → They are completely de-correlated, independent
    - → They have separated power supply, do not share underlying infrastructure
    - $\rightarrow$  If one DC fails, the other one is up and running

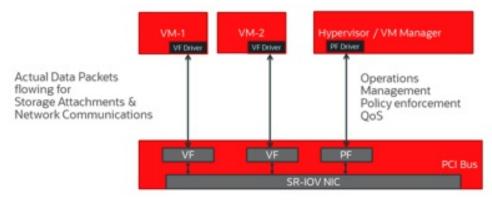

### **Off-box Network Virtualization**

- Gen 1.0 Cloud, inefficient Resource Sharing
  - On-Premise virtualization to share resources amongst multiple tenants in the cloud.

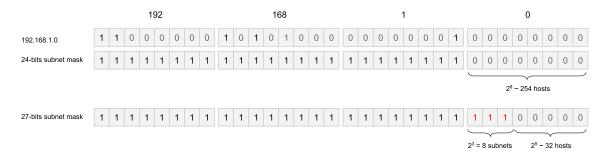

- Gen 2.0 Cloud
  - Smart-NIC accelerated SR-IOV (Single Root I/O Virtualization)
    - → Networking is a specialized function, needs hardware/sillicon to accelerate it

- Introduction
- Cloud Architecture
- Infrastructure as a Service
  - Networking
  - Compute
  - Storage
  - Infrastructure as Code

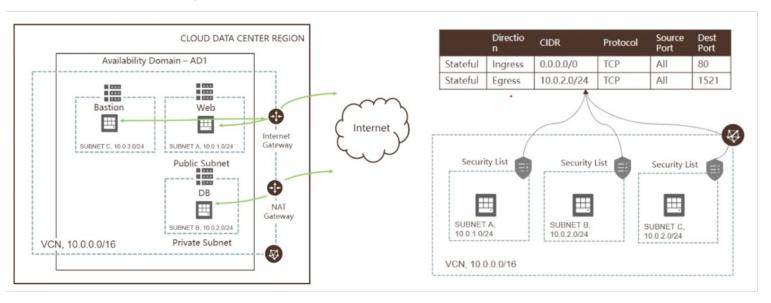

### **Virtual Cloud Network**

- VCN = a private network in a **single region** in which your instances reside
- A a single and contigous IPV4 CIDR block of your choice
  - CIDR (classless inter-domain routing) notation
  - IP address:
    - → network prefix (the most significant bits) and
    - → interfaces on the network (least significant bits) ~ network hosts
  - *Example:* 192.168.1.0/24
    - $\rightarrow$  *IP range:* 192.168.1.0 192.168.1.255
- You further create subnets on a VCN to organize your instances
  - The subnets must be "within" the VCN, they can span across ADs
  - Example: using 27 bits for a subnet mask allow for 8 subnets
    - $\rightarrow$  192.168.1.0/27, 192.168.1.32/27, 192.168.1.64/27, ...
    - → Each subnet can have 32 hosts

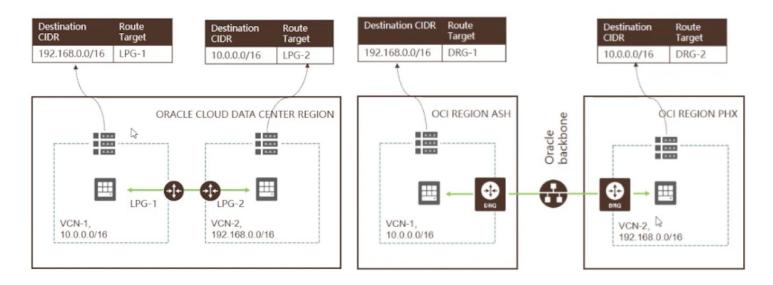

# **VCN** Routing and Security

- Private and Public subnets
  - Public can communicate in/out from/to Internet
  - Internet traffic routed to public subnet
  - Private can be completely isolated or communicate to Internet only
- Route tables
  - Required to route across subnets and in/out from the Internet
- Security
  - Control access to/from the subnet

# Peering

- Local Peering
  - Connecting two VCNs in a region
- Remote Peering
  - Connecting two VCNs across regions
- Connectivity with on-premise datacenter
  - Fast connection needs to be in place
  - Secure VPN needs to be established

- Introduction
- Cloud Architecture
- Infrastructure as a Service
  - Networking
  - Compute
  - Storage
  - Infrastructure as Code

# **Compute Instances**

- Shape = amount of memory and CPU an instance is using
  - There are classes of shapes that you can choose from
  - Standard and HPC/GPU shapes
- Virtual Machine (VM) multi-tenant model
  - A hypervisor to virtualize the underlying Bare Metal server into smaller VMs
- Bare Metal (BM) single-tenant model
  - Direct hardware access, full bare metal server
  - Types of workloads: performance intensive, require a specific hypervisor
- Dedicated VM Hosts (DVM) single-tenant model
  - VM instances running on dedicated single-tenant servers
  - *Not shared with other customers*

- States: start, stop, reboot, terminate
  - Billing pauses in STOP state but depends on shape

# **Image**

- Image
  - A template of a virtual hard drive with OS
  - Other software, libraries, configurations, etc.
- Stored on a boot volume
- Base images are provided
  - CentOS, Ubuntu, Windows Server, Oracle Linux, RedHat, etc.
  - Some may require licence costs
- Custom images
  - You can create a custom image from the base image
  - Specific packages, libraries or custom configuiration
  - You store the image in the object storage

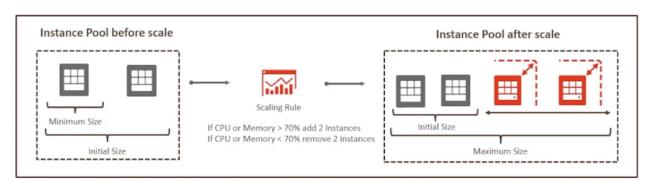

# Autoscaling

- Instance configuration
  - OS image, metadata, shape, vNICs, storage, subnets
  - Apply configuration to multiple instances at the same time
    - → You can manage them all together (start, stop, terminate)

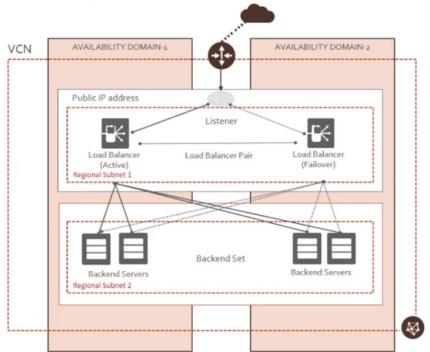

#### Autoscaling

- Automatically adjust a number of compute instances in an instance pool
- Control using performance metrics such CPU or memory utilization
- cooldown period time between scale in and scale out (e.g. 300 seconds)

### **Load Balancer**

- Managed service
  - Health check checks health status of backends (TCP, HTTP)
  - Algorithm round-robin, IP hash, least connections
- Supports protocols
  - TCP, HTTP 1.1, HTTP/2, WebSocket, SSL termination, end-to-end SSL
  - Supports sticky sessions (sessions persistence)
- High Availability
  - Primary and stand-by LB
  - Each LB is in different AD
  - Failover uses floating IP

- Introduction
- Cloud Architecture
- Infrastructure as a Service
  - Networking
  - Compute
  - Storage
  - Infrastructure as Code

# **Object Storage**

- Types of data to store
  - Storage for unstructured data (images, media files, logs, backups)
  - Data managed as objects, provides API using HTTP verbs
- Namespace
  - Logical entity that serves as top-level container for all bueckts and objects
  - Each tenancy is provided one unique namespace
- Bucket
  - A logical container for storing objects
  - Bucket names must be unique within tenancy
  - Hot bucket standard, can be accessed immediatelly
  - Cold bucket rarely accessed data, need to be restored
    - → Minimum retention, such as 90 days
    - → Time to First Byte (TTFB) is in hours, e.g. 4 hours
- Object and metadata
  - data managed as objects regardless data type
- Example object URL path:

/n/<namespace>/b/<bucket>/o/<object name>

# **Block Storage**

#### Local NVMe SSD device

- Locally attached device, provided by some shapes, 200K IOPS 1M IOPS
- Workloads that require high storage performance
- usually no RAID, snapshots, backups

#### Block volumes

- Reside in storage servers
- NVMe SSD based, up to 35K IOPS
- Data stored on block volumes beyond the lifespan of compute instance
- Multiple replicas across multiple storage servers

#### • File Storage

- Network file server (NFS)
- Client mounts a mount target (NFS endpoint) and an export path
- Example

sudo mount 10.0.0.6/example1/path /mnt/mountpointA

- Introduction
- Cloud Architecture
- Infrastructure as a Service
  - Networking
  - Compute
  - Storage
  - Infrastructure as Code

- Definition
  - Application envs (in a cloud) managed via definition files
  - Version control, team development, scripting, etc.
- Major Technologies
  - Configuration Management Tools
    - → install and manage software on machines that already exist
    - → Examples: Ansible, Chef, Puppet
  - Abstraction of cloud infrastructure
    - $\rightarrow$  Terraform

### **Terraform**

- Higher-level abstraction of the datacenter and associated services
- Supports many service providers
  - Google, Microsoft, Oracle, AWS
- Steps
  - 1. Description of resources in Hashicorp Configuration Language (HCL)
    - instances, networks, firewall rules, routing tables, etc.
  - 2. Terraform generates execution plan to reach the desired state
  - 3. Terraform executes the plan to reach the desired state; can generate incremental execution plan
