- Introduction
- Infrastructure as a Service
- Multitenancy
- Microservices Architecture
- Docker
- Kubernetes

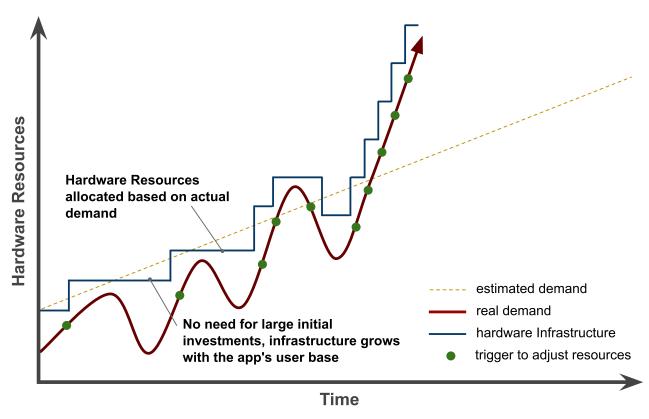

Traditional Solution to Infrastructure

- Traditional hardware model
 - *Up-front hardware investments*
 - Hardware not optimally utilized

Good Performance – Cloud Solution

- Cloud Computing model
 - No up-front hardware investments
 - Hardware optimally utilized

Cloud Computing Concepts

Resource Pooling

- Resources reused by multiple tenants (multitenancy)
- Resources: CPU, memory, storage, network

• On-demand and Self-service

- Resources are provisioned as they are requested and when they are required
- No human interaction, automatic

• Scalability and Elasticity

- Infrastructure may grow and shrink according to needs
- Automatic or manual

• Pay-per-use

- Consumers only pay for resources when they use them

Cloud Service Concepts

- Service Models (aka Cloud Layers)
 - IaaS Infrastructure as a Service
 - PaaS Platform as a Service
 - \rightarrow MWaaS, DBaaS, ...
 - SaaS Software as a Service
- Deployment Models
 - Public Cloud
 - Private Cloud
 - Hybrid Cloud
- Usage
 - Cloud native applications
 - Moving existing applications from on-premise to cloud

- Introduction
- Infrastructure as a Service
 - Infrastructure as Code
- Multitenancy
- Microservices Architecture
- Docker
- Kubernetes

Terminology (1)

- Region
 - A localized geographical area
 - A cloud provider usually has multiple regions around the world.
- Availability Domain
 - A datacenter in a region; there can be more AD in a region
- Tenancy
 - Isolated partition where a customer creates and organizes cloud resources.
- Instance
 - Compute host running in the cloud
- Bare Metal
 - Physical host that run directly on bare metal servers without hypervisor
- Shape/Class
 - Amount of computing resources allocated to the instance
 - CPUs, Memory, Local Disk, Network Bandwidth, Number of VNICs
- Image
 - A template of a virtual hard drive that defines operating system and other software for an instance.

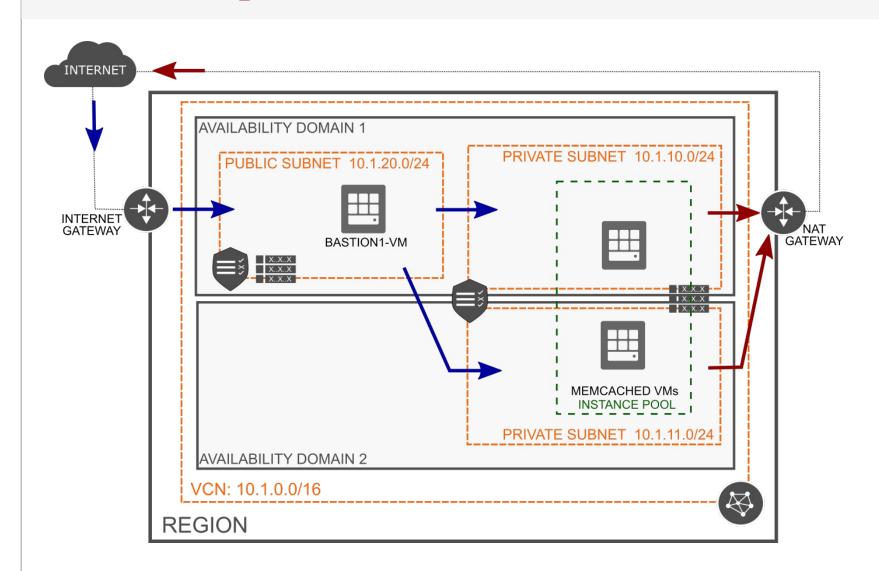

Terminology (2)

- Instance Pool
 - A group of instances
- Virtual Cloud Network (VCN)
 - A virtual network in which instances run
 - It includes: subnets, route tables, firewall rules, gateways
- Block Volume
 - A virtual disk providing persistent storage
 - It can be used as a volume attached to the instance
- Object Storage
 - Allows to store and manage data as objects in logical containers (buckets)
 - The data can be of any type and are usually of large size
 - The data does not change frequently
 - Examples: data backup, storing unstructured data, sensor-generated data

Access and Usage

- Layers
 - Cloud Infrastructure \rightarrow REST API \rightarrow CLI, Web Console, other tools
- Key pair
 - Authentication mechanism using **public** and **private** key
 - public key is uploaded to an instance, a client uses the private key to authenticate
 - Example: ssh using key authentication to access ssh deamon running in Linux

IaaS Example

- Introduction
- Infrastructure as a Service
 - Infrastructure as Code
- Multitenancy
- Microservices Architecture
- Docker
- Kubernetes

- Definition
 - Application envs (in a cloud) managed via definition files
 - Version control, team development, scripting, etc.
- Major Technologies
 - Configuration Management Tools
 - → install and manage software on machines that already exist
 - → Examples: Ansible, Chef, Puppet
 - Abstraction of cloud infrastructure
 - \rightarrow Terraform

Terraform

- Higher-level abstraction of the datacenter and associated services
- Supports many service providers
 - Google, Microsoft, Oracle, AWS
- Steps
 - 1. Description of resources in Hashicorp Configuration Language (HCL)
 - instances, networks, firewall rules, routing tables, etc.
 - 2. Terraform generates execution plan to reach the desired state
 - 3. Terraform executes the plan to reach the desired state; can generate incremental execution plan

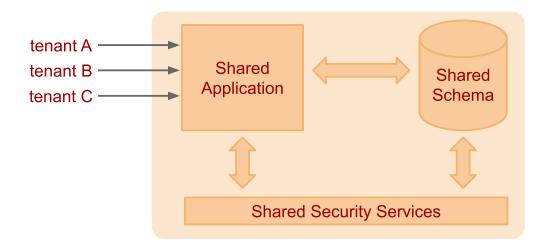

- Introduction
- Infrastructure as a Service
- Multitenancy
- Microservices Architecture
- Docker
- Kubernetes

Multitenancy

- Architectural approach where resources are shared between multiple tenants or consumers
- Implications
 - Centralization of infrastructure in locations with lower costs
 - Peak-load capacity increases
 - Utilisation and efficiency improvements for systems that are not well utilised
- Sharing options
 - Shared Everything
 - Shared Infrastructure
 - → Virtual Machines
 - \rightarrow O/S virtualization

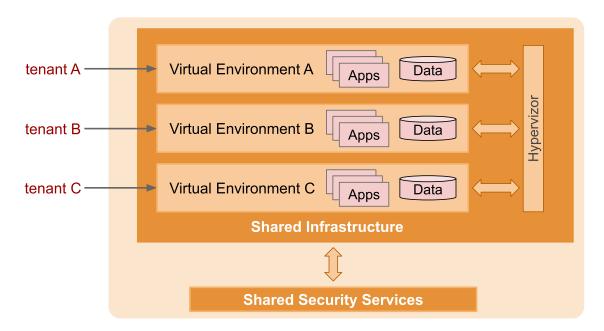

Shared Everything

- Resources are shared between all tenants or consumers
 - tenant: a service consumer
- Common for the SaaS model
- The application should provide tenant isolation
- Data for multiple tenants is stored in the same database tables

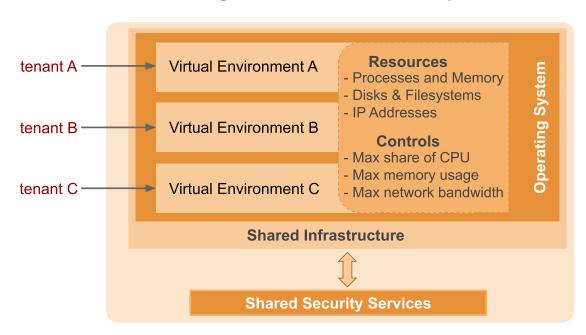

Shared Infrastructure: Virtual Machines

- Infrastructure shared via virtual machines
 - each tenant has its own virtual environment
 - Isolation provided by hypervisor
 - → hypervisor: virtual machine manager, runs virtual machines
 - Resource contention depends on VM capability and configuration
 - Adds an additional layer and processes to run and manage

Shared Infrastructure: OS Virtualization

- Infrastructure shared via OS Virtualization
 - Each tenant has its own processing zone
 - Isolation provided by the operating system
 - Resource contention depends on zone configuration
 - No VMs to run and manage, no abstraction layer between app & OS

- Introduction
- Infrastructure as a Service
- Multitenancy
- Microservices Architecture
- Docker
- Kubernetes

- Emerging software architecture
 - monolithic vs. decoupled applications
 - applications as independenly deployable services

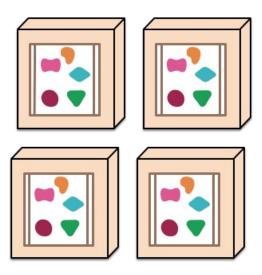

A monolithic application puts all its functionality into a single process...

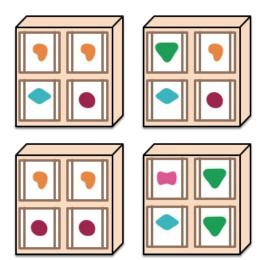

A microservices architecture puts each element of functionality into a separate service...

... and scales by replicating the monolith on multiple servers

... and scales by distributing these services across servers, replicating as needed.

Major Characteristics

- Loosely coupled
 - Integrated using well-defined interfaces
- Technology-agnostic protocols
 - HTTP, they use REST architecture
- Independently deployable and easy to replace
 - A change in small part requires to redeploy only that part
- Organized around capabilities
 - such as accounting, billing, recommendation, etc.
- Impplemented using different technologies
 - polyglot programming languages, databases

- Introduction
- Infrastructure as a Service
- Multitenancy
- Microservices Architecture
- Docker
 - Overview
 - Image Layering
 - Working with Docker
 - Swarm
- Kubernetes

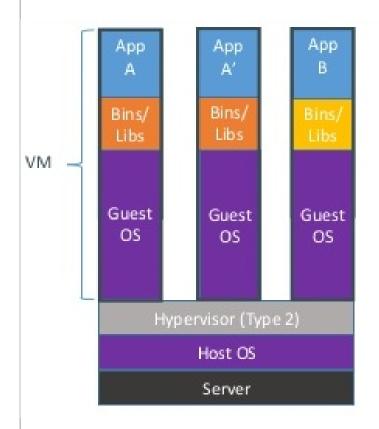

• Linux Containers

- Introduced in 2008
- Allow to run a process tree in a isolated system-level "virtualization"
- Use much less resources and disk space than traditional virtualization

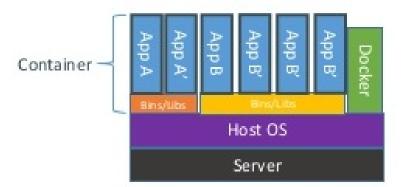

Implementations

- LXC default implementation in Linux
- Docker Containers
 - → Builds on new Kernel features: control groups (cgroups), kernel namespaces, union-capable file system (OverlayFS, AUFS, etc.)
 - \rightarrow A way to build, commit and share images
 - → Build images using a description file called Dockerfile
 - → Large number of available base and re-usable images

VM vs. Docker Containers

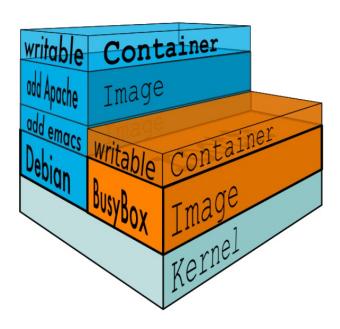

Containers are isolated, but share OS and, where appropriate, bins/libraries

Docker Basic Terms

- Image
 - Bssis for containers.
 - An image contains a union of layered filesystems stacked on top of each other.
 - An image does not have state and it never changes.
- Container
 - A runtime instance of a Docker image, a standard to "ship software".
- Docker Engine
 - The core process providing the Docker capabilities on a host.
- Docker Client
 - Interface that integrates with docker engine.
- Registry
 - A hosted service containing repository of images.
 - A registry provides a registry API to search, pull and push images.
 - Docker Hub is the default Docker registry.
- Swarm
 - A cluster of one or more docker engines.

Docker Images

- Containers are made up of R/O layers via a storage driver (OverlayFS, AUFS, etc.)
- Containers are designed to support a single application
- Instances are ephemeral, persistent data is stored in bind mounts or data volume containers.

- Introduction
- Infrastructure as a Service
- Multitenancy
- Microservices Architecture
- Docker
 - Overview
 - Image Layering
 - Working with Docker
 - Swarm
- Kubernetes

Image Layering with OverlayFS

OverlayFS

- A filesystem service implementing a union mount for other file systems.
- Docker uses overlay and overlay2 storage drivers to build and manage on-disk structures of images and containers.

Image Layering

- OverlayFS takes two directories on a single Linux host, layers one on top of the other, and provides a single unified view.
- Only works for two layers, in multi-layered images hard links are used to reference data shared with lower layers.

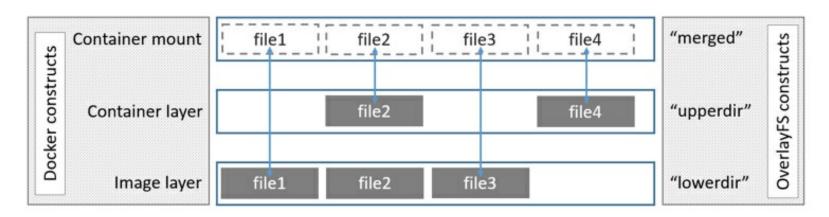

Image Layers Example

• Pulling out the image from the registry

```
$ sudo docker pull ubuntu

Using default tag: latest
latest: Pulling from library/ubuntu

5ba4f30e5bea: Pull complete
9d7d19c9dc56: Pull complete
ac6ad7efd0f9: Pull complete
e7491a747824: Pull complete
a3ed95caeb02: Pull complete
Digest: sha256:46fb5d001b88ad904c5c732b086b596b92cfb4a4840a3abd0e35dbb6870585e4
Status: Downloaded newer image for ubuntu:latest
```

- Each image layer has its own directory under /var/lib/docker/overlay/.
- This is where the contents of each image layer are stored.
- Directories on the file system

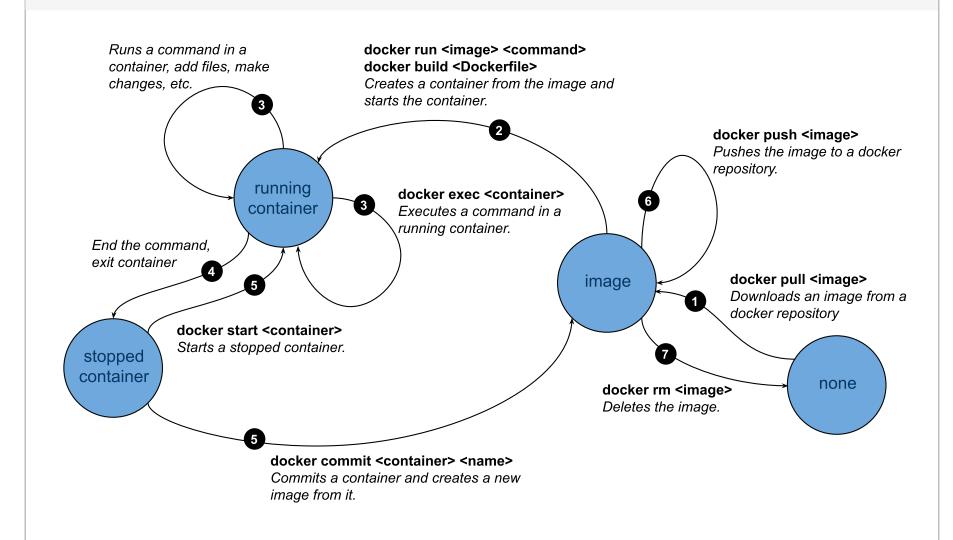

```
$ ls -l /var/lib/docker/overlay/
```

```
total 20
drwx----- 3 root root 4096 Jun 20 16:11 38f3ed2eac129654acef11c32670b534670c3a06e483fce313d72e3e0a15baa

```

- The organization of files allows for efficient use of disk space.
- There are files unique to every layer and hard links to files shared with lower layers

- Kubernetes

Docker Container Lifecycle State Diagram

Commands (1)

docker version

list current version of docker engine and client

docker search <image>

search for an image in the registry

docker pull <image[:version]>

download an image of a specific version from the registry if the version is not provided, the latest version will be downloaded

docker images

list all local images

docker run -it <image[:version]> <command>

start the image and run the command inside the image if the image is not found locally, it will be downloaded from the registry option -i starts the container in interactive mode option -t allocates a pseudo TTY

docker ps [-as]

list all running containers option -a will list all containers including the stopped ones. option -s will list the container's size.

Commands (2)

```
docker rm <container>
    remove the container

docker rmi <image>
    remove the image

docker commit <container> <name[:version]>
    create an image from the container with the name and the version

docker history <image>
    display the image history
```

Networking and Linking

- There are 3 docker networks by default
 - bridge container can access host's network (default)
 - → Docker creates subnet 172.17.0.0/16 and gateway to the network
 - → When a container is started, it is automatically added to this network
 - → All containers in this network can communicate with each other
 - host − all host's network interfaces will be available in the container.
 - none container will be placed on its own network and no network interfaces will be configured.
- Custom Network configuration
 - You can create a new network and add containers to it
 - Containers in the new network can communicate with each other but the network will be isolated from the host network
- Linking containers (legacy)

```
$ docker run -d --name redmine-db postgres
$ docker run -it --link redmine-db:db postgres /bin/bash
root@c4b12143ebe8:/# psql -h db -U postgres
psql (9.6.1)
Type "help" for help.
postgres=# SELECT inet_server_addr();
postgres=# SELECT * FROM pg_stat_activity \x\g\x
```

Networking Commands

docker network 1s

lists all available networks

docker network inspect <network-id>

Returns the details of specific network

docker network create --driver bridge isolated_nw
 creates a new isolated network

docker run -it --network=isolated_nw ubuntu bin/bash
starts the container ubuntu and attaches it to the isolated network

Data Volumes

Data Volume

- A directory that bypass the union file system
- Data volumes can be shared and reused among containers
- Data volume persists even if the container is deleted
- It is possible to mount a shared sotrage volume as a data volue by using a volume plugin to mount e.g. NFS
- Adding a data volume

```
docker run -d -v /webapp training/webapp python app.py will create a new value with name webapp, the location of the volume can be determined by using docker inspect.
```

Mount a host directory as a data volume

```
docker run -d -v /src/webapp:/webapp training/webapp python app.py if the path exists in the container, it will be overlayed (not removed), if the host directory does not exist, the docker engine creates it.
```

- Data volume container
 - Persistent data to be shared among two or more containers
 docker create -v /dbdata --name dbstore training/postgres /bin/true
 docker run -d --volumes-from dbstore --name db1 training/postgres
 docker run -d --volumes-from dbstore --name db2 training/postgres

Dockerfile

• Dockerfile is a script that creates a new image

```
# This is a comment
FROM oraclelinux:7
MAINTAINER Tomas Vitvar <tomas@vitvar.com>
RUN yum install -q -y httpd
EXPOSE 80
CMD httpd -X
```

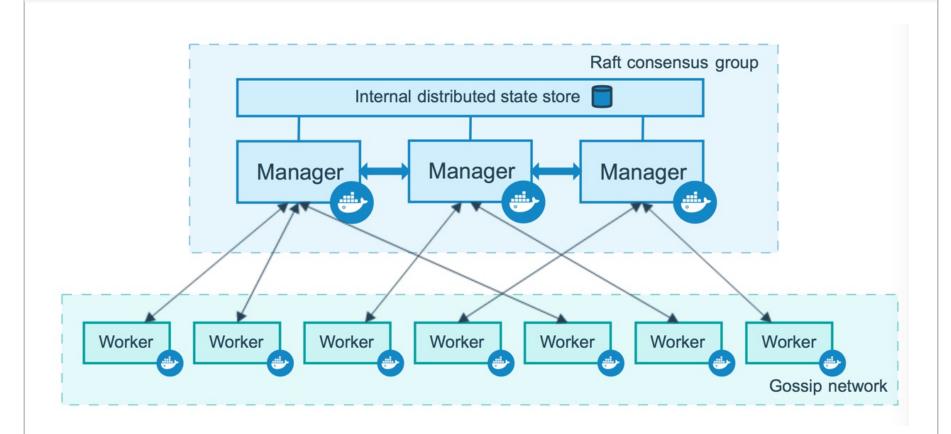

• A line in the Dockerfile will create an intermediary layer

```
$ docker build -t tomvit/httpd:v1 .
Sending build context to Docker daemon 2.048 kB
Step 1 : FROM oraclelinux:7
---> 4c357c6e421e
Step 2 : MAINTAINER Tomas Vitvar <tomas@vitvar.com>
 ---> Running in 35feebb2ffab
 ---> 95b35d5d793e
Removing intermediate container 35feebb2ffab
Step 3 : RUN yum install -q -y httpd
---> Running in 3b9aee3c3ef1
---> 888c49141af9
Removing intermediate container 3b9aee3c3ef1
Step 4: EXPOSE 80
---> Running in 03e1ef9bf875
 ---> c28545e3580c
Removing intermediate container 03e1ef9bf875
Step 5 : CMD httpd -X
 ---> Running in 3c1c0273a1ef
```

If processing fails at some step, all preceding steps will be loaded from the cache on the next run.

- Kubernetes

Swarm

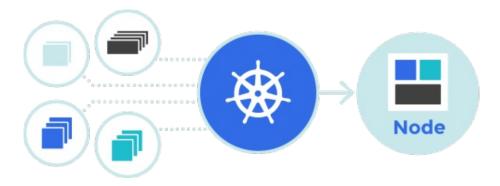

- Introduction
- Infrastructure as a Service
- Multitenancy
- Microservices Architecture
- Docker
- Kubernetes

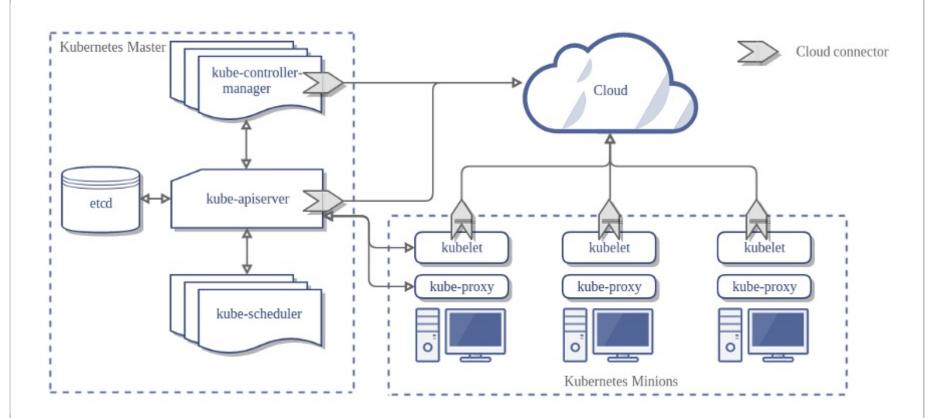

- In your architecture...
 - Containers are atomic pieces of application architecture
 - Containers can be linked (e.g. web server, DB)
 - Containers access shared resources (e.g. disk volumes)

Kubernetes

- Automation of deployments, scaling, management of containerized applications across number of nodes
- Based on Borg, a parent project from Goolge

System Architecture

Major Terms

Node

- a worker machine in Kubernetes, previously known as a minion (a VM or physical machine). It uses kubelet and kube-proxy to communicate with the master and other nodes/services.

Master

- A node that manages the cluster of nodes.

Pod

- The basic building block of Kubernetes, one or more dependant containers.

Service

- A set of pods with rules allowing pods to talk to each other, such as:
 - \rightarrow NodePort *exposes the pod under a cluster IP.*
 - → LoadBalancer exposes the pod for load balancing by external load balancer

Controllers

- Worker units to ensure a desired state, such as:
 - \rightarrow ReplicaSet ensures that a specified number of pod replicas are running.
 - → Deployment manages ReplicaSets, provides declarative updates to pods.
 - \rightarrow StatefulSet manages deployment and scaling of a set of Pods.
 - → DeamonSet ensures that all (or some) Nodes run a copy of a Pod.

Features

Automatic binpacking

- Automatically places containers onto nodes based on their resource requirements and other constraints.

Horizontal scaling

- Scales your application up and down with a simple command, with a UI, or automatically based on CPU usage.

Automated rollouts and rollbacks

- Progressive rollout out of changes to application/configuration, monitoring application health and rollback when something goes wrong.

Storage orchestration

- Automatically mounts the storage system (local or in the cloud)

• Self-healing

- Restarts containers that fail, replaces and reschedules containers when nodes die, kills containers that don't respond to user-defined health checks.

Service discovery and load balancing

- Gives containers their own IP addresses and a single DNS name for a set of containers, and can load-balance across them.

Demo

- Environment Setup
 minikube a local virtual machine (running a master and a single node)
 kubectl CLI to access Kubernetes cluster
- Steps
 - 1. create hello-node app in node.js and test it [see server.js] node server.js
 - 2. create docker image for the app [see Dockerfile]
 docker build -t hello-node:v1 .
 - 3. deploy the app to Kubernetes by using kubectl kubectl run hello-node --image=hello-node:v1 --port=8080
 - 4. Expose the app as a load balancer service. kubectl expose deployment hello-node --type=LoadBalancer
 - 5. Explore the app in minikube dashboard. minikube dashboard
 - 6. Fire requests at the service and count them [see test.sh]./test.sh.
 - 7. Change the number of replicas by using the dashboard or kubectl.
